netic iron ores, specular iron ore, red hæmatite, and micaceous iron, and numerous hydrates, called brown hæmatites. There are also spathic iron, brown spar, and clay ironstone. Silicates and phosphates of iron are also sometimes used. The richest ores are the protoxides; the next the peroxides; and the least rich, but most abundant, the carbonates, or rather the carbonates of the oxide. The phosphates are sometimes rich in iron, and the silicates also. The former are chiefly worked in Canada; the latter near St. Maurice, and in the Canton of the Valais, in Switzerland. The sulphides are valued only for the sulphur they contain. Magnetic iron ore is a rare mineral in England. It is diffused in the old rocks, but is not abundant. The chief supplies are from Norway, Sweden, and Russia. The central portion of the island of Elbe is of this material. Important veins of it exist in India and the East, in North America, in Mexico, and in Brazil. It contains, when pure, 72 per cent. of iron. The hæmatites are more common with us than magnetic ore. They are rich in iron, but it is more profitable to mix them with the poorer ores than to use them alone. There are two kinds; one yielding, theoretically, 69½ per cent. of iron, and the other 56 per cent. The ores are rarely free from foreign substances. The crystalline are either specular ores, micaceous ores, or oligist. The earthy ores are opaque and red, whence the name "hæmatite," or blood-stone; but when containing water, this colour passes into brown. They are valuable for smelting. They are also used for polishing; and some varieties are employed as pigments. The carbonates of iron, yielding from 20 to 45 per cent. of metallic iron, are sometimes crystalline, as in sparry iron, but more often earthy, as in the common ores of most parts of England. They form the group of clay ironstones. The chief mines of hæmatite in England are at Ulverston and the neighbourhood of Whitehaven. at the bottom of the limestone in contact with slate. At Todholes, near Cleator, this ore is worked as a quarry. The floor of the deposit is a white and red mottled shale of the limestone series, almost a fire-clay, and 40 feet thick. The surface of the shale is uneven, and is covered by white quartz pebbles. Then comes a magnificent bed of hæmatite, from 15 to 30 feet thick (sometimes as much as 60 feet), subdivided by irregular joints. Bands of greenish-black shale are interstratified with this ore. It is difficult to say whether the ore is a contemporaneous deposit. It is extracted in the manner adopted in the case of coal, and the quantity removed is large. Besides these mines, the same ore has long been worked from the carboniferous limestone of Low Furness, in a deposit resembling a chasm or vein, and at Dalton, under similar circumstances. Curious dis-

shaped deposits of hematite exist in the same neighbourhood. Some of these are 50 yards in width, and 20 yards deep. The ore in them is only covered by drift. The ore is fine and crystalline. From one point you may proceed 400 to 500 feet in either direction in one solid mass of this valuable substance, and its bottom has not been reached. Other hematites are from Derbyshire, the forest of Dean, Somersetshire, and South Wales. Those of the forest of Dean seem almost inexhaustible. The coal measures are equally rich in clayey iron ores. They are impure; earthy, and carbonaceous minerals, among which iron oxide is present to a large extent. The clay ironstones are black, blackish-brown, yellowish-brown, pale yellow or drab. They are sometimes regular bands and sometimes groups of nodules alternating with coal-bearing deposits. In the Bradford districts (Yorkshire) there are groups of bands near the bottom of the coal measures: the upper group contains five bands, which are valuable though not pure. They contain 36 per cent. iron oxide and 25 per cent. carbonic acid, besides nearly 20 per cent. of silica. In Derbyshire the ironstones are numerous, and they yield from two to six thousand tons per acre. The most remarkable is the "Black shale," of Stavely, near Chesterfield. It consists of two groups: the upper containing nine, the lower twelve seams, half an inch to 1½ in. in thickness. The Shropshire and North Staffordshire coal-fields yield some excellent qualities of ore adapted for making the best kinds of iron, but the quantity per acre is not large, nor are the ironstones rich. In the Potteries coal-field the ironstone bands are in the upper part of the field, agreeing with South Staffordshire and North Wales. The ironstones of these districts include the black bands, originally worked in Scotland. In South Wales, the coal measures form two series, the lower containing the great bulk of the iron bands. These may be followed across the Bristol Channel to Ireland, but are there poorer than in Wales, yielding an average of less than 20 per cent. Scotland is exceedingly rich in similar ores. Within a few years enormous deposits of iron ore have been obtained from the Cleveland Hills, in the east of Yorkshire. On the coast there crops out a thickness of fifteen feet of ironstone, containing an average of 30 per cent. of metallic iron, but, unlike an ore, resembling an iron sandstone, its surface deeply rusted. It occupies the position of the marlstone in the middle of the lias formation, and extends over a region of some hundreds of square miles, thinning out towards the south. The supply must be regarded as practically indefinite, and it is obtained with extreme facility. Its yield at one point near Euston, has averaged 50,000 tons per acre, and the available ore per acre would average 49,000 tons, yielding 10,000 tons of metallic iron. In France, also, the oolitic rocks are partly made up of rich ores and of iron, the ores being earthy and not easily recognised, except by those who trust to analysis instead of appearance. The value of such ores is about equal to that of English oolitic ores, the general average being about 30 per cent. The most remarkable beds of ore are in the centre of France, not far from coal. Belgium and Germany are not less rich in valuable ores than France; but they are not always available for the manufacture of iron, as, without fuel, the richest iron ores are of little value. The value of ironstone depends much on the supply of fuel at hand, and thus the ironstones of the coal measures, though not rich, are important; while it is only from accident that other ores possess the value now attributed to them. In the north of Europe, where there are forests, and cheap labour, charcoal iron may be made of the pure ores of these countries; and in India, smelting can be carried on to advantage in small furnaces, but these are exceptional conditions. The methods of obtaining iron ore vary according to the position of the ore, the magnitude of the deposit, and the presence of other useful minerals. In the lias and oolites, the ores are removed by digging or quarrying. In the coal measures they are

raised with the coal. The system of bell pits is adopted where the ironstone nodules of the lower coal measures come close to the surface. There are small shafts arranged in great numbers on the line of strike at a distance of a few yards from each other, and in the Forest of Dean the ore lies in open spaces in the limestone, called "churns," or "pockets." In mining it is cut away, leaving natural pillars. The contents of the deposits vary, both in quality and quantity, and the result is a picturesque irregularity, strongly contrasting with the monotonous galleries of coal mines. To utilise the poorer ores of iron, admixture of other mineral is needed in the furnace. This is called a flux. With the common ores limestone is a flux. The richer ores can be reduced at once with charcoal in small quantities; the great operations of iron smelting are confined to those countries where the claystones and limestone abound, and where there is also an abundant and cheap supply of mineral fuel. Everything thus resolves itself into a question of coal. Where there is coal other things are at hand. When coal is absent other mineral wealth is comparatively useless. Too much attention cannot be given to the history of mineral fuel, that we may know where to expect deposits and how to obtain them. There are many varieties of mineral fuel differing in their properties and in the circumstances of their occurrence. I do not include among coal the shales which simulate coals, and are sometimes reckoned as part of them, but only the coals strictly so called, namely, the anthracite and bituminous varieties and lignites or brown coal. Some have no value for commercial purposes, but their carbon contents are all strongly marked, and the carbonates afford the best measure of their relative practical utility. Lignites are inferior to coals. They are irregularly distributed in rocks of the tertiary period. They are so far altered as to have a mineral aspect, but they retain a woody character. They exist sometimes in masses of enormous dimensions, but not in regular beds. In England they have no value, but in Germany there are important deposits. This kind of fuel labours under a great disadvantage. It contains water (at least 10 per cent.), which only is got rid of by drying in the air. Lignites contain much ash. Thus, when burnt, much of the heat is left in the conversion of the contained water into steam; and part is wasted on the ash. But lignites are not to be despised as fuel. They have been found available for manufacturing purposes, for iron smelting, for railways, and for steam-boats. In the valley of the Rhine, on the shores of the Baltic, and in Styria, are some of the thickest of these deposits, approaching 200 feet in thickness. The very best lignites may be detected on exposure. After a short time they change, and in a few months fall to powder. They must thus be brought into use immediately after coming out of the mine. Most of the newer deposits of mineral fuel are lignites. The exact reason of this is not clear. It was long regarded as an axiom in geology, that no coals were deserving of the name but the carboniferous period. Real coal exists, however, not only in secondary rocks, but in tertiary. This is proved by the contents of a remarkable coal-field in the valley of the Zsli, in Transylvania. There, in tertiary sands, are regular seams of excellent coal, very thick, and standing every test. Chalk, the oolites, and the lias also contain coal. In England the Kimmeridge coal is a rich bituminous shale. The Brora field possesses two seams, worked by pits sunk 80 or 100 yards. The coal is bituminous, and burns to a white ash. The Whitby coal has been worked more than a century, and is of fair quality. There is excellent oolitic coal on the Danube. One deposit is at Fünfkirchen, not far from Pesth. Though poor in appearance, and powdery, this coal burns well, with flame and much heat and without much ash. The Ovacza coal is inferior to the Fünfkirchen; but supplies the Vienna and Danubian railroads. Asiatic coals are chiefly from oolitic rocks. There are five coal districts—three in Northern India, one in Ouch, and the fifth on the coast of the

Burman empire. The coal is associated with limestones, clays, and ironstone bands. The South African coal is from rocks of the same age. A large tract in Eastern Virginia contains valuable oolitic coal, worked near Richmond. There are three seams, one of them 30 or 40 feet thick; the total thickness about 30 feet. The coal is adapted to the manufacture of gas, but varies in different parts of the field. The great coal fields of England, of Belgium, of Spain, of France, and of North America, besides those of Bohemia, Moravia, and the Rhine, of Russia and China, and probably of Australia, belong to the Palaeozoic rocks. The coal-fields of Great Britain range from Somersetshire, in the south, to Ayrshire, Lanarkshire, and Fifehire, in Scotland, in the North. There are four principal groups of deposits, distinguished as the Northern, Eastern, Western, and Southern. These again are subdivided, and we have, in a different order, the following coal-fields:—(1) the Newcastle coal-field, (2) the Cumberland and Westmoreland coal-fields, (3) those in the West Riding of York, (4) the South Lancashire coal-field, (5) the Flintshire coal-field, (6) the great Yorkshire and Derbyshire coal-fields, (7) the North Staffordshire, (8) the Coalbrook Dale and other Shropshire coal-fields, (9) the Worcestershire coal fields, (10) the Leicestershire, (11) the Warwickshire, (12) the South Staffordshire, (13) the Forest of Dean, (14) the British and Gloucestershire group, (15) the South Welsh coal-field. In Scotland, in the valley extending from the Firth of Forth to the Firth of Clyde, we have (16) the Clyde Basin, (17) the Ayrshire coal-field, (18) the Leamhago Basin, (19) the Clinkmannan coal-field, (20) the Fifehire, (21) the Lothians, and (22) the Dumfries. All supply bituminous coal and some also yield cannel coal, steam coal, or anthracite, and all are liable to faults of all degrees of magnitude, and every variety of condition. The faults are sometimes mere interruptions of continuity, but sometimes wide gaps filled with stones or rubbish. There is no doubt of the vegetable origin of coal; but it still remains a mystery how coal was formed, or what combinations were necessary to produce it. In most cases it represents a mass of vegetation that must have taken many years, or a large area, to accumulate, but yet in some instances there is proof that it must have accumulated rapidly. It seems to have accumulated near the mouth of large rivers or low swampy flats. Bituminous coal is brittle, burns with flame and smoke, and gives off gas on dry distillation. It contains from 10 to 30 per cent. of volatile substances, and leaves a residue of coke. Caking coal is a variety which runs together in the fire. Cannel coal, or parrot, is compact, does not soil the fingers, and can be sculptured. It burns like a torch or candle, with much light and smoke, and contains from 40 to 60 per cent. of volatile substances. Steam coal is a hard semi-bituminous coal, with little volatile matter, but burning freely with flame and much heat. Anthracite is free carbon, homogeneous, and with conchoidal fracture. Some varieties are powdery or flaky; some resemble graphite. The Newcastle coal-field (1) has been the most extensively worked of any. Till lately it yielded bituminous coals and cannel, it now also yields excellent steam coal. Its coal is valued for household use, and it makes the finest coke. No anthracite has been found here. The area occupied by coal contains about 700 square miles, and is divided by a great fault crossing the whole field from east to west, the strata being lowest on the northern side of the fault by ninety fathoms. There are no important bands of ironstone. There are forty seams in the Newcastle field, but only eighteen are workable. The most valuable is two yards thick. The total thickness of workable coal is eighty feet, and the mean thickness of workable coal four yards. Some of the best seams are worked out to a considerable depth. Estimating the area of 450,000 acres, the average thickness at four yards, and the weight of the coal at one ton per cubic yard, the field would contain eight thousand millions of tons of coals. The Whitehaven field yields valuable coal. Its extent, with two other small fields

adjacent, is 100,000 acres. There are seven workable seams, the thickest of which is eight feet. They are worked under considerable difficulties, and at great depths, sometimes beneath the sea. The coal is good and caking. The South Lancashire coal-field (4) supplies the vast population concerned in the manufactures carried on in that part of the kingdom. The coal occupies an irregular area. It is found not only in the coal measures, but in the millstone grit, and the whole area includes a thousand square miles of strata. Many of the coals are thin, and the sections are unequal. In one direction there are 75 beds of coal in 2,000 yards of measures, the total thickness of coal being 150 feet. In another direction there are only 26 seams, though the total thickness of coal is 90 feet. The thickest bed is ten feet. The quality is good. There is excellent cannel worked near Wigan and elsewhere, particularly valuable for gas. The available coal has been estimated at 4,000,000,000 tons, but the evidence is very imperfect. The sinkings are not deep, and the quantity of water is not excessive. The Flintshire and Denbighshire coal-field (5) is smaller and much worked. There are five workable seams, of which one is nine feet thick. The total thickness of coal is nearly 40 feet. Among the beds is a cannel, called curly cannel, extremely rich in hydrocarbons. The Yorkshire coal-field (6) supplies many large towns in the north of England. The number of seams is not large, but one of them is ten feet thick, and there more than thirty feet of workable coal. The quality is excellent, and the pits of moderate depth. There are also very numerous bands of ironstone. The North Staffordshire or Pottery coal-field (7) contains a number of good seams of excellent coal. Here there is forty feet thick of coal, in twenty-four seams, one of which is ten feet thick. With the coals are ironstones. The South Staffordshire coal (12) is brought up by faults through the new red sandstone. It has one seam, called the "ten-yard seam," exceptional among the English coals. In other countries are many beds of coal that bear the same proportion to this that the thick coal of Staffordshire does to the six-foot coals of Newcastle. The Forest of Dean has been less worked than some, but is of considerable importance. Near it, in Gloucestershire, is another small coal-field. Near Bristol there is an extensive and important coal district, now much worked, and yielding a large supply of excellent fuel. We come next to the great South Welsh coal-field (15), which includes 900 square miles. It is divided into three unequal parts; the west anthracitic, the middle steam coal, and the east bituminous. With the coals is ironstone; generally thin, but of good quality. The thickness of coal is 70 to 100 feet. Although the estimates of the total quantity of coal are exaggerated, it is the largest and most important in the British islands, and its resources will be available long after the smaller coal areas of the north have been exhausted or rendered unworkable. The Scotch coal-fields are both numerous and rich. Most of the coals are dry, free burning, but not caking. They belong to the lower members of the carboniferous series, and are older than the English coals. The total area is 1,600 square miles. Coal has been long worked in Scotland, and the total quantity raised amounts to 12,000,000 tons. An important part of the Scotch coal is made use of for distillation, to obtain paraffin oils. Ireland has coal-fields, both bituminous and anthracitic. The former are small, but the coal is abundant. The anthracitic deposits are more numerous and more worked than the bituminous. The coal of Munster is the most developed. Belgium is rich in coal, and the province of Hainault, the western division of the coal-field, is very remarkable. Every variety is found there—from pure anthracite, burning without flame, through the rich bituminous kind called "*Charbon gras*," making excellent coke, to the flaming coal or cannel called "*Fléau*." The most valuable of all is called "*Charbon maigre à longue flamme*." France possesses a very large number of small coal-fields. Those in the northern departments are portions of the Belgian

coal-fields, and contain the same varieties of coal. In the eastern part of the country, as at Saarbrück, on the Moselle, there are others of the same nature. In the interior the most important are in and near the Basin of the Loire. In central France there are numerous small basins, in some of which the thickness of the coal is extraordinary. At Aubin there are 124 yards of solid coal in eight seams, one of which measures fifty yards at its outcrop. In Rhenish Prussia the basin of the Ruhr, near Düsseldorf, is the seat of important coal mining operations, and the Saare coal-field extends from France into Germany. The chief German coal-fields are those of Bohemia and Silesia, Moravia and Galicia. The total yield of bituminous coal from the Austrian empire in 1860 was about one and a-half million tons. Some of the rivers of Russia, and some localities on the shores of the Black Sea yield good coal. The Iberian peninsula is very rich in coal. In the Asturias, there is a coal area of very large dimensions, containing upwards of a hundred workable seams, varying from three to twelve feet in thickness. In the south of Spain, in Portugal, and near Barcelona, there are workable coal seams. There are coal seams almost within the arctic circle. North America contains coal-areas, compared with which the richest deposits of Europe sink into insignificance. The chief are the coal-field of the Alleghenies, including the basin of the Ohio and the coal-field of Illinois; the basin of the Missouri, and the coal-fields of Nova Scotia, New Brunswick, and Cape Breton. The Allegheny coal-field measures 750 miles in length with a mean breadth of 85 miles, and traverses eight principal States, among which are Virginia, Pennsylvania, Ohio, Kentucky, and Alabama. Making a liberal deduction for unproductive portions, denuded strata, and unattainable depths, there are 25,000,000 acres of valuable coal-field. The coal is partly bituminous, partly anthracite, and the seams numerous and convenient. The Illinois field includes the Indiana district, where a rich bituminous coal extends over an area of 8,000 square miles. There is another great coal-field in Missouri. British America supplies coal in New Brunswick, Nova Scotia, and Cape Breton. The New Brunswick beds are thin. Nova Scotia is extremely rich, and contains one seam of thirty-four feet of good coal, besides others of ordinary proportions. The coal is excellent. South America contains coal on the coast of Brazil. China and Japan possess mineral fuel extending down the eastern side of Australia, where coal has been long worked. The Chinese coals were worked at least six centuries ago, both anthracitic and bituminous. New Zealand contains coal. Borneo has large deposits. The methods adopted to obtain coal constitute the practice of mining; they vary according to the position of the coal, the thickness of the seam, the nature of the rocks above and below, the quality of the coal, and the quantity of gas it gives off underground. The quantity of water also enters into consideration. If coal crops out on the side of a valley, it can be got readily, and at small expense, by levels or galleries tunnelled into the side of the hill. Coal, however, being rarely horizontal, a gallery, following the dip of the coal, will incline down-hill on one side and up-hill on the other side of the valley. In the first case any water that enters will escape, but in the other it will accumulate. The coal also can be run out readily in the one, and must be drawn up-hill at some expense in the other. Thus, it is only when coal is horizontal or dips towards a valley, that crop workings can be carried on with advantage. In the other case it will be better to sink a pit and obtain the coal by running a drift from the bottom of this pit. Crop workings are confined to the early workings on a seam. Coal at its outcrop may sometimes be obtained by quarrying when the seam is thick, and retains its quality as a useful fuel after long exposure to the weather, but in England such workings have long ceased to have much value. Among the more remarkable open workings is one at St. Etienne, near Lyons, in France. When underground works are to be reached by a pit or shaft, it becomes a

matter of importance to know whereabouts, at what depth, and in what state the coal lies. Where the outcrop is known, the dip of the coal regular, and the coal not faulted, this is not a difficult task. But the permanent inclination of a coal seam is not always the same as its dip at the outcrop, and faults must not be left out of calculation. Better ground for an opinion than calculation is therefore necessary, and boring must be resorted to, that we may learn the general relations of the beds and the depth to a known point in the series, after which calculation is easy. Three borings are necessary where the coal is not already proved, and its outcrop is not clearly known. Several are required when there is reason to expect faulted ground. When all is known that can be made out concerning the circumstances under which the coal lies in any given property, the next operation is to sink a shaft to intersect the bed at a certain depth, so that all that is possible of the coal seams of the district may be worked. Great experience is needed to decide this point. On the one hand, if the pits are too deep, unnecessary expense is incurred, not only at first, but afterwards, in getting as well as reaching the coal, and in lifting the water. On the other hand, if they are so placed as not to be able to remove the coal from the extremity of the estate, that portion will be lost; for after expensive pits have been sunk, and much of the coal got, it will not be worth while to get the rest by a fresh sinking. So with regard to faults, if the pits be sunk without reference to them, great difficulty may be experienced and heavy expenses incurred that might be avoided by greater knowledge of the ground. When coal is being got from near the outcrop, it is usual to sink many more shafts than when the mine is deep. The enormous cost of deep shafts justifies this economy, but there are both disadvantages and great dangers in mines that are carried on by a single shaft or by shafts too far apart. In the event of an accident, either to the shaft or in the ventilation, communication may be entirely cut off, and thus a heavy loss of life may result. Thus the determination as to the number and position of the shafts is a matter to be very carefully considered. In shallow mines, the pits are generally single and of moderate size. In deep mines, they are in pairs, or one very large shaft is divided into three portions. A shaft or shafts being decided on, the work of sinking commences. The rocks through which the sinking has to pass will some of them be water-bearing beds, and would supply strong springs, if that were the object of the sinking. If water is reached while sinking, it must be shut off; if it comes in at the bottom, it must be pumped out. The only way of shutting it off is by lining the shaft with an iron casing passed down as the sinking proceeds. The bottom of the shaft is the coal seam which it is intended to remove. When the coal is reached, and there are two pits, these are immediately connected, partly for ventilation, and partly for the convenience of further workings. One pit should be free, and serve as a chimney for carrying off the air, which is injured by the breathing of the men, or by emanations of gas from the coal. During the sinking of each pit, if more air is wanted than naturally comes down, the shaft is divided into two portions by a partition, and ventilation is effected by artificial means. If there is a pair of pits close together, they are usually sunk on the line of dip of the beds, so that one shall reach the coal at a greater depth than the other. In this case a natural ventilation sets in, one shaft acting as a chimney to carry heated air up, and the other as a pipe down which the heavier air descends. When coal is reached, a drift or tunnel is carried on it in the direction of the strike. In the case of a pair of pits two such drifts are cut, one from each. This enables the field to be laid out conveniently, and reveals the condition of the coal, the state of the roof, and the continuity of the seam. Along these roads the coal when removed can be drawn. Along the lower drift, or by the side if there is a single pit, the water of

the mine is conducted, and when there is a pair of pits, the lower of the two drifts is called the water-gate, and the upper the horse-gate. At right-angles to such drifts, and on the rise of the coal, another gallery is driven, called the winning headway, or, in Yorkshire, the main board-gate. If there be a second shaft at a distance, it is convenient that this should communicate with the winning headway. The further working of the mine may be carried on either by the pillar and stall or the long wall method. The former is adopted in the Newcastle coal-field, and has been introduced with modifications into many other districts. The latter is that followed in the coal-fields of Yorkshire. In the Newcastle coal-field, where the coal lies deep, where there is much water, and where shafts are costly, and the coal full of gas, it is found convenient to divide the coal property into a number of panels, or divisions, kept separated by a thickness of forty or fifty yards of coal. Each panel is worked independently, beginning with that most distant from the shaft. Levels are driven at right angles to each other, leaving large pillars of coal to keep up the roof, till the whole panel is laid open. When such galleries have been completed the pillars are attacked, carrying away as much as possible, supporting the roof for a time with wooden pillars, and ultimately removing the pillars, and allowing the roof to fall. The farthest panel being removed, the next may be attacked, and so on till the work is completed. In Yorkshire, where the depth is less and the coal harder, with fewer less troublesome, the long wall method is adapted. By this, drifts are run through the coal from the main board gate parallel to the winning headway, and the coal is left in a number of long walls supporting the roof. When the mine is thus laid open, the walls are entered by small cross drifts, and the greater part removed, and the roof allowed to fall. In coal mines, there is a cause of difficulty and danger arising from the light carburetted hydrogen gas existing in the coal and emitted under ground, especially where the coal has recently been broken. Besides this fire-damp, choke-damp, or carbonic acid gas, is not unusual. Both have to be provided against by ventilation, and thus the conveyance and distribution of air is essential in laying out a coal mine. Mixed with atmospheric air, this light gas, when exposed to flame, explodes, leaving after explosion carbonic acid gas and a small quantity of water. When a large quantity of gas issues from coal, and mixes with the atmospheric air carried down for ventilation, as soon as the proper mixture is obtained the light from an open candle would explode the whole, leaving behind a poisonous, heavy gas, which must inevitably choke those who have not already suffered by the explosion. By the ventilation of mines, dangerous mixtures of gas should be rendered as unlikely to occur as possible, and, by a safe method of lighting, the danger, when it exists, should be avoided. But perfectly safe ventilation and a perfectly safe light are not easy to find, and accidents still occur from neglect of proper precautions. The ventilation of mines is conducted by producing a strong draught up one shaft by means of a fire at the bottom, or by exhausting the air by steam or other means at the top. All the air entering the mine by the other shaft or shafts is forced to take a course through the workings, and along the levels, before reaching the up-cast shaft. Extreme care and attention is needed to ensure the ventilation being adapted to the issue of gas, and to avoid a dangerous mixture. But a safety-light is needed, even where the ventilation is most perfect and best looked after. Such a light was provided in the Davy lamp, and it is theoretically perfect if the explosive gas in the mine be light carburetted hydrogen, and if due caution be used. This lamp is a common oil lamp, covered with a metallic gauze, so open that little light is intercepted, but so close that flame cannot pass. The gas poured into a mine from certain kinds of coal, or from empty spaces met in working coal, is sometimes large in quantity, and issues with so much force as to overcome all efforts to render it safe by mixture

with atmospheric air. In such mines there is a constant singing heard, especially where the coal is newly broken. In such cases the use of the safety-lamp is necessary, if indeed it is right to carry on work at all. Gas accumulates in old workings, and when these are reached, either in continuing the works of the same mine, or in any other way, there is great danger. Many of the worst and most fatal accidents have happened in this manner. When coal has been removed the roof will fall, or if supports are left, the pressure on the floor will drive that up. There must thus in all neglected works be a vast pile of broken rock in which great open spaces are left, and in these the gas becomes stored. Such a pile is called the "goaf," and the depression that appears at the surface when the roof of a mine is fallen is called "creep." These are a few of the many points that suggest themselves in reference to the practical geology of coal-mining.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 8th, 1865; Lieut.-Colonel J. P. Kennedy in the chair.

The following candidates were proposed for election as members of the Society:—

Newcombe, Cornelius Prout, 16, Barnsbury-villas, Liverpool-road, N.
Perkes, Samuel, West Dulwich, S.
Scott, Colonel, R.E., Ealing, W.
Tanqueray, Arthur Charles, Hendon, Middlesex, N.W.

The following candidates were balloted for and duly elected members of the Society:—

Giles, Francis, 42, Blomfield-road, Maida-hill, W.
Phillips, Major Thomas Scott, 10, College-crescent, Finchley-road, N.W.
Savile, Edward B., 80, St. George's-road, Pimlico, S.W.
Spriggs, William, 10, York-row, Kennington-road, S.
Templetown, Major-General Viscount, C.B., Government House, Devonport.
Walker, Micajah Hilditch, 13, St. Swithin's-lane, E.C.
Warden, J. William, Warwick Cottage, Park-village East, N.W.
Yardley, Vincent, 3, Thorney-street, Bloomsbury, W.C.

The Paper read was—

ON THE GINNING OF COTTON.

By ZERAH COLBURN, Esq., C.E., Memb. Inst. Civil Engineers.

It was for a long time the habitual boast of the planters of the Southern States of America that "Cotton was King, that it ruled England, and that they, the planters, ruled cotton." The American civil war itself was in some measure due to this delusion. In renouncing Federal authority the Southern people, then unprepared for war, were almost unanimous in the belief that England would interpose, either by diplomacy or by arms, as might be necessary, to prevent any interruption in her supply of cotton.

In 1860, when our total consumption of this great staple was 1,088,000,000 lbs., exceeding that of any previous year, five-sixths of that supply was drawn from America. Last year we consumed but 561,000,000 lbs., or about one-half as much as in 1860, and of this less than one-twelfth was drawn from the once United States. In other words, nineteen-twentieths of the American supply has been lost to us, and with the failure of the recent negotiations for peace and with the certainty of the overthrow of American slavery, no one can pretend to say when any portion of this loss will be recovered. At present the mills of Lancashire are mostly supplied from India, the larger proportion of Indian cotton being grown in the Central and Western provinces, and shipped from

Bombay. The virtual monopoly which the Indian cultivators now enjoy cannot, however, be said to have resulted either from the force or the policy of British rule in the East. Nor is India as well suited as some other countries to the growth of good cotton. The indigenous staple is of inferior quality, and the country needs irrigation before a good return can be had from exotic seed. It has been rather our necessity, and the growing commercial influence which this country exercises in India, that has brought forward such large supplies upon such short notice.

Previous to the American war, no country in the world could have competed successfully with the Southern planters of the States in the growth of cheap and excellent cotton. In 1849, the quality known as fair New Orleans was as low as 4½d. per pound in Liverpool, and it averaged no more than 6d. for a series of years. The Mississippi low lands will produce yearly from 250lb. to 500lb. of clean cotton per acre, or nearly five times as much as in the best cotton districts in India. The American planter is his own landlord, and beyond the interest on the cost of his farm and of his slaves,—the latter cultivating crops for their own food also—his labour costs him next to nothing. Before the war he was lightly taxed, even under the indirect taxation of a protective tariff upon articles of consumption imported from abroad. The American cotton country, too, is intersected by great navigable rivers, affording the cheapest possible means of communication by steamboats and by barges. Added to this, the staple of the American, or more correctly, the Mexican seed cotton (which is of that quality known as New Orleans) is sufficiently strong to bear the action of what will be presently described as the saw gin, a machine for separating cotton from its seed at the rate of from two to seven bales per day. Hardly any other than the Mexican seed cotton will bear the saw gin, and hence, heretofore, no other staple could as a rule be so rapidly and cheaply ginned. As gathered from the shrub, the fine filaments of cotton are firmly attached, at one end, to a hard but oily seed, not quite so large as the kernel of a filbert. This seed is covered with cotton on all sides, and the value of this depends upon the length, fineness, strength, and colour of the filaments. These are flattened, twisted tubes, with no joints; whereas the filaments of flax are cylindrical, jointed tubes. Cotton fibres vary in diameter from the $\frac{1}{160}$ th to the $\frac{1}{100}$ th of an inch, or about one-third the diameter of fine human hair. Their length varies greatly. Inferior cottons have a staple not longer than $\frac{1}{4}$ ths of an inch; the New Orleans middling variety is about 1½in., while the very fine Sea Island cotton sometimes reaches a length of 2½in., or even more. The short-staple cotton grows from a greenish-coloured seed, which, even after ginning, has a woolly surface, while the finer cotton, as the Sea Island, has a smooth black seed, from which the filaments are easily detached. Of a given weight as it comes from the field, only from one-fourth to one-third is cotton, the remainder being seed. From their great comparative weight, if for no other reason, the seeds must be separated from the cotton at the place of growth, as otherwise the cost of freight to market would be tripled or quadrupled.

It would be an intolerably tedious process to pick the cotton from the seeds by hand labour. Not much more than one pound of clean cotton, or lint, as it is always called on the American plantations, could be thus separated per day. From a very early period, however, the Hindoos have cleaned their seed cotton by passing it between a pair of smooth wooden rollers revolving nearly in contact with each other. This machine is known as the churka, and is still used in India. The rollers, by their revolution, draw the filaments of cotton between them and thus away from the seed, upon which, from its size and hardness, the rollers cannot bite. Smaller rollers of steel, fluted with fine grooves along their length, so as to increase their tractive force upon the filaments of cotton, are still made and used to some extent in separating Sea Island cotton from its seed.

The word "gin," as applied to machines, is a contraction of the word engine, and the churka is undoubtedly the most ancient cotton cleaning engine or gin in existence.

On the conclusion of the American war of independence in 1781, the people of the Southern States of the new Union turned their attention to the cultivation of cotton, for which the then increasing use of Arkwright's spinning machinery had already created a considerable demand at high prices. With a rich soil and congenial climate, and with the economy of slave labour, crops to almost any extent could be cheaply raised. But the separation of the cotton from the seed presented a great difficulty. Hand labour for this purpose was even then out of the question, while the churka, known in America as the roller gin, was so ineffective that two or three days' work of even forty slaves, each employed in feeding and turning a gin of this kind, would result in but a single bale of clean cotton, often the produce of but a single acre of land. Each slave labourer will cultivate cotton to the extent of five bales yearly on the uplands of Georgia, and from ten to fifteen bales on the lowlands, but it would require the constant work of the same labourer, at a churka, for nearly three months to separate even one bale of clean cotton from the seed. At the Royal Exhibition held last year at Turin, a large number of cotton gins, of all kinds then known, were carefully tested for quantity and quality of work. Among them was a churka made and in considerable use in Italy under the name of Manganello. With a pair of $\frac{1}{2}$ in. wooden rollers 8in. long, worked by one man at the rate of 89 revolutions per minute, only six ounces of cleaned Siamese cotton were turned out per hour, and probably not more than half a pound per hour from like gins could have been counted upon by the American planters in the last century. The Sea Island and the upland cotton were first planted in the States in 1789, but many planters who thus commenced soon abandoned this branch of culture. It happened at this time that a Yankee schoolmaster, Eli Whitney, then resident in the family of an influential Southern planter, had his attention directed to the then great want—that of a machine or gin for quickly and cheaply separating cotton from its seed. Whitney hit upon a revolving circular saw, as the most effective instrument for the purpose. Not that the saw acts by incision, as in its common application with wood, but its teeth, which are filed to the form of sharp conical claws, seize hold of and pull away the cotton from the seed, the seed being held back by the fixed sides of a narrow opening through which the saw is made to revolve, much as a circular saw, in wood working machinery, revolves between the sides of a narrow slit in the saw-bench. It is a little doubtful whether Whitney, at that time, had seen a circular saw in use for cutting wood, but had he done so, the whole idea of his gin might have been caught from such a saw at work. With a saw shaft once in revolution, it was evident that a number of saws might as well be mounted upon it, each working between the sides of its own guard, for stopping the seeds, and thus, it would be right to suppose, the effect of the machine would be directly as the number of saws employed. Whitney understood this, and he fixed a considerable number of saws at short intervals upon a single shaft, and these worked with but little clearance at their sides between the bars of a kind of a gridiron, or grid. A revolving cylinder with projecting brushes was added to clear the cotton from the saw teeth after it had been drawn through the grid. Whitney completed his invention and patented it in 1792, and it is impossible to say how much the cotton trade now owes to his simple and effective contrivance. The early machines turned out 300 lb. of clean lint per day, while at the present time a gin of sixty or seventy nine-inch saws, driven by steam at a speed of 180 to 200 revolutions per minute, will deliver 3,000 lb. of clean cotton in twelve hours, an amount about equal to the average yearly crop cultivated by a single slave labourer. As an inventor, Whitney's fame in the States

is co-extensive with that of Fulton, and his tomb, at New Haven, Connecticut—modelled after that of Scipio, at Rome—bears a glowing eulogy to his genius.

When we consider the exceedingly delicate character of loose filaments of cotton, it is a matter of wonder that they bear the discipline of the saw gin at all. Indeed, it was soon found that the fine Sea Island cotton was cut to pieces in saw ginning, as the long-stapled Egyptian cotton, if it were tried, would also be. It is to the credit of the American or Mexican "Orleans" and Georgia staples that it does bear the saws. Other cottons, however, do not possess the same strength and elasticity. The indigenous Indian, Chinese, and Turkish cottons will not bear the saws, and they require careful treatment in any process of ginning. On the occasion of the International Exhibition of 1862, Mr. Wanklyn, a well-known Lancashire cotton spinner, sampled and valued all the cotton exhibited. Much of it had been spoiled—literally chopped to bits—in ginning, and a still larger quantity had been more or less injured, so as materially to lessen its value. The difference between good and bad ginning, as applied to the case of the whole present Indian cotton supply, would amount to a difference of between six and ten millions sterling in value yearly.

The American or Mexican cotton may be grown elsewhere, however, than in America. Its seed has been transplanted in Brazil, in India, and in some other countries. The New Orleans seed was introduced into India in 1842, by Mr. A. N. Shaw, the collector in the Dharwar district of the Bombay presidency. At one time the result was reported a total failure, and this report appeared under Government auspices. It is the fact, however, that Dharwar cotton, of all others in India, is the most extensively cultivated, while it brings also the highest price. It is believed by many that the New Orleans seed has degenerated since its introduction into India, yet Dr. Forbes Watson's reports show that much of the Dharwar cotton has a staple of from 1½ in. to 1¾ in., and, in some cases, even 1¾ in. long, and of a very fine quality. All the Dharwar cotton is saw-ginned, after the American practice, and it is believed to be the only Indian-grown cotton that will bear the saw gin. Dharwar, although in the Southern Mahratta country, and near the Madras Presidency—in fact, not many miles to the eastward of the Portuguese colony of Goa—is commonly reckoned, in respect of its production of cotton, with the district supplying what is known as Surat cotton, or Surate, from the port of that name to the northward of Bombay. "Surate," in Lancashire, has become a term indicative of everything bad, from beer to theology. Indeed, one of the Manchester newspapers, not long since, incurred and lost an action for slander, in consequence of the unintentional admission of an advertisement, in which the produce of a firm of brewers was spitefully nicknamed "Surate." Much short, yellow, weak-stapled cotton, filled with leaf and stones, has undoubtedly been shipped under this name from Bombay to England; but the Dharwar cotton deserves a different classification. With proper means of communication it is probable that the cotton of the Dharwar and other districts of the Deccan will be yet shipped from the new port of Sedashagur, nearly half-way between Bombay and Beyppoor, the latter being the western terminus of the Madras railway.

Without entering fully into the moot question whether cotton will thrive permanently in the East, it is early certain that the Dharwar, or transplanted staple, is the only one now in India which can be saw-ginned without much loss by cutting, and without the formation of knots or "neps" of fibres, which sadly try the fine teeth of the carding engines, and which if once produced in ginning, will infallibly cause the production of lumps in the yarn. The American cotton has this advantage, so, in favour of the grower: with a given crop of seed cotton, requiring a given amount of labour in its cultivation, from three-tenths to one-third are obtained as

clean lint, whereas nearly all other short-stapled seed cottons give one-fourth only of their weight in lint. In other words, the American seed, on Indian soils, gives nearly one-fourth more clean cotton, for the same acreage and labour, than any of the indigenous sorts.

The Macarthy gin, as it is named from its Irish-American inventor, who produced it about thirty years ago, was designed for staples that are too tender to bear the saw-gin. Its action is at once simple and unique, and it may be described as that of rubbing the fibres from the seed, or, more strictly, pulling them from the seed by a rubbing process. The construction and action of the Macarthy gin will be better understood, perhaps, from a familiar illustration than from drawings and a technical description. The roller of a jack towel, revolving nearly but not quite in contact with a kitchen wall, will convey the idea very closely. And, without wishing to make out a case for the interference of the Society for the Prevention of Cruelty to Animals, a Skye terrier will serve as a magnified as well as animated representative of the seed, with its cotton growing from all parts of its surface. With so much suggested it is easy to understand how a mischievous boy would proceed to gin a favourite poodle, and if the poor brute were not fleeced, and possibly flayed in the operation, he would have nature and not his tormentor to thank for it. But if we pursue this illustration we shall see that, if the roller were sufficiently large and turned with sufficient force, it would "bite"—to use the technical term—not merely the hair but the dog also. So, instead of the kitchen wall, we will place the edge of kitchen shovel along the roller, so as nearly to scrape its revolving surface, this edge being presented not towards the centre of the roller, but tangentially to its circumference. If, now, we cover the towel roller with leather, so as to increase its frictional power, we shall have the Macarthy gin. The revolving leather-covered roller pulls the cotton through the narrow space which separates it from the fixed tangential blade, or "doctor," as it is called, and the seeds are kept back because they are too large and too hard to pass through. The action may be compared to that of the churka, although there is some difference. The advantage which the Macarthy roller has over the churka is that the former may be made of any convenient diameter, and thus its surface speed may be increased much beyond that of the small rollers of the churka; and, furthermore, as the larger roller has sufficient stiffness to prevent springing sideways in its work, it may be made of any convenient length—say, 20 in., or even 40 in., whereas, the churka rollers are seldom more than 8 in. long.

In addition to the fixed blade of the Macarthy gin there is a second blade parallel with it, and put in rapid motion, so as to alternately overlap its edge, and thus to roll the seed cotton about, so that every portion of its surface may be fairly brought to the fixed edge of the "doctor." A grid is provided, of such width of opening that the seeds can only pass through it and escape after they have been completely stripped of their cotton.

Different makers have added various parts to the Macarthy gin, until, in some cases, it has become a complicated and a costly machine. One of these, in the International Exhibition of 1862, with a profusion of rollers, wheels, &c., representing an accumulation of alleged improvements, was said to turn out about 40 lbs. of clean cotton per week for each inch of the length of the roller, or, say, 1,000 lbs. of cotton for a 24-inch roller. The delivery of cotton depends upon the quality under treatment, and twice as much Sea Island, or even Egyptian cotton, could be ginned in a given time as could be turned out with Syrian or the shorter-stapled Indian sorts. At the Exhibition held last year at Turin, a large number of gins, of different kinds, and mostly by English makers, were tested with great care. The report of the Commissioners charged with the experiments gives the dimensions of the several gins, the speed at which they worked, the quantity and kind of seed cotton ginned,

the quantity of seeds and clean cotton delivered, the temperature of the air at the time, the hygrometric state of the cotton, &c.; and also the power expended, as ascertained in the case of the steam-gin, by means of a dynamometer. The results were so widely various as to defy the application of any law; but it may be said that the very best, in the case of a gin with a single Macarthy roller, 5in. in diameter and 40in. long, worked at the rate of eighty revolutions per minute for only fifteen minutes, was at the rate of rather less than 22lbs. of cleared Italian cotton per hour. Another trial of the same gin, at the same speed, for eleven minutes, gave a rate of 18lbs. only of cleared cotton per hour. A gin of the same size, by another leading maker, and worked at the rate of 125 revolutions per minute for 14 minutes, delivered at the rate of 14½ lbs. only of cleaned cotton per hour. As a rule the shorter rollers—say, 20in.—gave a better result in proportion to their length, because, no doubt, the labour in feeding, being applied to a shorter distance along the roller, was relatively more effective. In one case a gin, with a 4½in. Macarthy roller, 40in. long, driven, in successive trials, at the rates respectively of 73, 138, and 107 revolutions per minute, turned out cleaned cotton at the hourly rates, respectively, of 1½ lb., 12 lb., and 8½ lb. only. If anything like an average result could be drawn it was that the gins with a single Macarthy roller did not average over 5 lb. or 6 lb. of clean cotton per hour, at which rate it would take more than a week to gin a bale of cotton. The Macarthy gin does its work well so far as the condition of the clean fibre is concerned, and, were it not that its action is so tedious, and therefore so costly, a great aggregate saving would be effected by ginning even American cotton upon it. But this is totally out of the question, for if a penny or so per pound were thus added to the value of cotton, this would be more than lost in the greatly increased cost of ginning as compared with the saw gin. The Macarthy roller, too, is constantly wearing out, and has to be covered anew every few weeks, at a cost from £2 to £4. The leather frequently strips off at once from the wooden roller, and it is especially liable to deteriorate in hot countries. To avoid these difficulties finely-grooved iron rollers have been employed, the grooves running spirally around the roller. But these are not found to answer well, although they are, no doubt, very durable. In other cases rollers formed of circular discs of paper, compressed with great force upon each other, are in use, although here the frictional power or tractive force upon the cotton is less than that of leather. Indeed, the proverb appears to have held good, that "there is nothing like leather" for the rollers of the Macarthy gin. The tremor caused by the rapid movements of the vibrating knife, worked by a pair of short cranks, making from 500 to 700 revolutions per minute, is an objection to the gins now generally made upon the Macarthy principle. The vibrating knife, too, in many cases, interferes with instead of assisting the access of the seed cotton to the ginning roller. This was remarked upon in the case of several of the gins worked at the Turin Exhibition. Again the feeding requires constant attention, and, even at the best, it is irregular. The cotton cannot, of course, be expected to come off in an even fleece, like the thin and beautiful web from the doffer of a carding engine, but, very far from this, it ordinarily leaves the Macarthy roller in lumps and patches, falling irregularly both as to time and as to the length of the roller. Thus although the whole quantity ginned may be but little, too much may get through at one point, heating the roller to such an extent as to destroy the leather.

The last annual report of the committee of the Cotton Supply Association observed, as to the cotton gins, that "much yet remains to be done to provide what is urgently needed, to wit, a machine which, without injuring the staple as the saw gin often does, shall approximate to it in productive capability. Your committee regard this as a matter of vital importance to the cultivation of cotton." This opinion of the committee is that of every person well

informed upon the subject. It is already a matter of much complaint that even the Dharwar cotton in India, the only kind grown there that will bear the saw gin, is being spoilt by the ryots who plant the indigenous and the exotic seed together, the result being a mixed staple, perhaps half of which is so injured in saw ginning as to render the whole nearly worthless. Whatever, too, may be the case of Indian cotton cultivation at present prices, anything like a return to those which prevailed five or six years ago will depend upon a very great improvement in gins. As applied to the prospective cotton crop of India, the advantage of a gin which, while nearly as efficient as Whitney's, shall make as good work as Macarthy's, may be valued at ten millions sterling per annum, or, if capitalised at ten years' purchase, to one hundred million pounds. This is but a practical and reasonable estimate of that which the committee of the Cotton Supply Association consider, to use their own words, "a matter of vital importance to cotton cultivation."

So long as ginning is a mechanical operation (and it has not been yet proposed to employ chemical agencies in the separation of cotton from its seed) so long must the staple be forcibly pulled from the seeds, which must be held back by the narrowness of the space through which the staple is drawn. The clawing action of the saws, the direct pull of the churka, and the rubbing pull, if the term may be allowed, of the Macarthy roller, would appear to exhaust all the modes in which force can be properly applied for the purpose to seed cotton. It is not certain what improvements, if any, can be made upon the saw gin. Certain modifications have been made, but the saws, to which all the injury to weak staples is attributable, are still the same in all gins of this class. A far more likely direction in which to look for improvement would be in that of the Macarthy gin, and here, it is not now premature to say, an improvement has been lately made which appears likely to raise this class of gins to the position contemplated in the extract quoted from the report of the Cotton Supply Committee. It is easy to see, on looking at a Macarthy roller at work, that a great portion of its surface, perhaps 40in. wide and running at the rate of 150ft. per minute, is altogether ineffective. Where something like an unbroken cascade of cotton should fall from it, it delivers in dribbles. This scattered and patchy delivery proves that the appliances for feeding the roller are not what they should be; and this fact is a matter of course where constant hand feeding is required, as in nearly all the gins heretofore made of this kind. The travelling lattice and feed rollers sometimes employed do not act with anything like the effect on seed cotton that they do upon the cleaned staple in the opener, or the lap in the carding-engine. Seed cotton has very little cohesion in the mass, and it objects to march in close rank up to the sharp blast of the ginning roller. But by urging it forward, and distributing it continuously along the whole length of the fixed blade, the tractive force of the leather-covered roller may be increased, perhaps, four or five-fold beyond the ordinary rate. These objects appear to have been fully accomplished in the new gin invented by the gentlemen of the North Moor Foundry Company of Oldham, Messrs. Brakell, Günther, and Hoehl. In addition to the Macarthy roller and fixed blade or "doctor," they employ what is called a "knife roller," revolving in an opposite direction to the ginning roller, and at about four times the velocity. The knife roller, of which an example is shown, is a stout tube of gas pipe, with journals at the ends, and having upon it a number of discs or washers, placed obliquely to its axis. As the knife roller is rapidly revolved these discs not only draw the seed cotton into the ginning roller, but they distribute rapidly and alternately to the right and left along the edge of the "doctor." The knife roller is of the same diameter as the ginning roller, and the oblique discs or washers upon the former are from 1½ in. to 2 in. apart, and have such an obliquity, with reference to the axis of the roller, that

the whole of the seed cotton is rapidly traversed right and left along the doctor to about the same distance of $1\frac{1}{2}$ in to 2 in. From the form of the oblique discs the change from the right to the left-hand motion, and *vice versa*, although made at very short intervals, is, nevertheless, gradual. The whole improvement consists in the application of the simplest possible means to produce a constant in-draught of seed cotton, and to distribute it constantly along the ginning roller, all parts of which are thus made to do their share of work. Instead of arguing, however, as to what the action of the knife roller ought to be, it is better to give the results actually obtained in practice.

With a ginning roller twenty inches long the author has varied the knife roller gin with the following results:—At 152 revolutions per minute of the ginning roller, at which there was but the slightest heating of the leather coverings, the rate of cleaned Syrian short-stapled cotton delivered was 28 lbs. per hour. Of African cotton, of a slightly better quality, the rate was 31 lbs. per hour. Of Egyptian cotton, with hard black seed, the rate was 46 lbs. per hour. These rates may be taken as quite double that attained by any other gin of the same dimensions on the Macarthy principle. The seeds were very thoroughly cleaned, showing no waste; the fibre was not cut or torn in any manner, and, indeed, there was nothing to tear it. Nor was it at all knotted into those obstinate little entanglements which the Manchester spinners call “neps,” and which, while they throw the teeth of the carding engines out of pitch and out of shape, and give, perhaps, fifty different diameters to a single yard of yarn, cause sad infractions of proper language among the spinners themselves. To turn out a large quantity of clean and uninjured cotton without waste is all that is expected of the best gin, and this the new knife roller gin undoubtedly accomplishes. It is, moreover, of extreme simplicity, having but three wearing parts—the ginning roller, the knife roller, and the “doctor,” with but a single pair of spur wheels to gear the two rollers together. The usual objectionable cranks and rapid vibratory motions are altogether dispensed with. The gin is self-feeding, in virtue of the action of the knife roller, and thus a single attendant can manage a number of gins.

These results are confirmed by many of the leading mechanical engineers and cotton spinners of Lancashire who have seen the new gin at work, and the results stated may, therefore, be considered as accepted by those responsibly engaged in those branches of trade connected with the manufacture and working of cotton gins.

The makers of the knife roller gin have also produced what promises to be an improvement upon the Macarthy roller. Instead of a plain roller with a leather jacket, they have formed a compound roller of alternate discs of leather and malleable cast iron, the latter smooth on their circumference, but having corrugations on their sides near the edge. This roller appears calculated to exert a greater average tractive force upon the cotton, and to be more durable than the rollers now in use, and it is not likely from its action to injure the staple. Whether further trial should or should not fully confirm these expectations the novel and excellent action of the knife roller is not less established, and to this alone the great superiority of the new gin may be attributed.

Efforts are now making to grow cotton wherever it can be cultivated with the prospect of fair and good crops. As a great textile staple, cotton must be always in demand, and just as this demand is met so must the price fall until only a fair price is realised on the prime cost of production, with a due interest on the capital invested. As the price of cotton falls the relative importance of cheap and expeditious ginning will increase. With cotton as now as from 18d. to 2s. per pound for middling staples, even a penny a pound, as the cost of ginning, is not relatively large, but with anything like a return to 6d. per pound even $\frac{1}{4}$ d. for ginning would be a very serious item in the total cost. As one means of improving the general condition of the Indian cotton trade, therefore, and of

enabling it to hold its own, permanently, against competition from all other sources, the author has brought to the notice of the Society of Arts what he believes to be the best instrument yet contrived for ginning cotton. When once this conviction is shared by this Society, perhaps no other agency than theirs could be more effective in making known the truth throughout the great cotton producing districts abroad. At the present juncture no subject is perhaps more worthy serious consideration on the part of the council and members of this Society—especially charged with the duty of encouraging the arts and manufactures—than that of the cheap and perfect separation of cotton from its seed—a matter upon which the permanent prosperity of the Indian cotton trade in a very great measure depends.

DISCUSSION.

Mr. VASLEY remarked that the comparison made by Mr. Colburn between the fibres of cotton and flax was incorrect. It was stated that the filaments of cotton consisted of “flattened twisted tubes, with no joints, whereas the filaments of flax are cylindrical, jointed tubes.” He submitted that there was no joint whatever in the fibre of flax, the apparent joint being only a cross filament. Many years ago an attempt was made to “cottonise” flax by soaking it in alkali, and afterwards in acid; but the process damaged the material. Experiments he had made with filaments of flax, showed them to be neither tubular nor jointed, but quite solid. He believed flax to be the best material for the manufacture of cloth.

Mr. A. NABBETT SHAW said, his name having been mentioned in the paper, he requested permission to say a few words on this subject. With respect to the question of gins generally, the first consideration was to adapt them to the particular kind of cotton on which they were intended to operate, as it was obvious from what was stated in the paper that the description of machine which was adapted for one quality of cotton would be injurious to another. Without going through all the different varieties of cotton, he would divide them generally into the two kinds of green seed and black seed cotton. Amongst the latter might be classed all the indigenous cottons of India. Hitherto they had been unable to introduce the better qualities of cotton into India without the aid of irrigation. These were perennial, and no doubt, with the aid of irrigation, would yield three or four good pickings a year. He considered if the Government of India had done its duty the better qualities of cotton would have been cultivated in that country to a very much larger extent. The New Orleans was the only exotic cotton grown in India as an ordinary crop; and in speaking of the relative commercial value of New Orleans and indigenous cotton, he might be allowed to quote a few sentences from a paper on this subject which he read two years ago before this society, in which he stated:—

“New Orleans still maintained its position at the head of the price current, being on the 12th of November, 1862, 150 rupees per candy higher than the best cotton in the Bombay market. . . . Allowing that it requires seven acres of the New Orleans seed to produce a candy, or 784 lbs. of clean cotton, and that thirteen acres of the indigenous cultivation are necessary to yield an equal amount (the relative prices of the New Orleans and indigenous cottons being as quoted in Bombay at the above date, 560 rupees and 390 rupees per candy), the difference of the value of 280,000 acres of these respective cultivations, taking the rupee at two shillings, would be as £2,240,000 to £840,000, leaving in favour of the New Orleans £1,400,000, to be divided amongst those concerned in India in growing and selling the crop, and manifold more valuable to the Government and country than the whole aggregate of the expenditure which has been incurred in all the experiments throughout India.”

Looking at this statement, it was obvious that the cotton to be introduced into India was the New Orleans; and in the South Mahratta district there were very nearly

half a million acres of that cotton now under cultivation. It was well known that during the old time of the monopoly of the East India Company very little cotton came to this country from India. What they could acquire through their agents was bought up and sent to China in exchange for tea. They might have introduced every description of cotton into India if they had desired it, but under the monopoly of the East India Company they neglected to do so. After that monopoly was broken up, the manufacturers of Manchester took up the question, and frequently urged the East India Company to improve the quality of cotton grown in India, seeing that the trade had fallen completely into the hands of the Americans. Under that pressure the East India Company did what they no doubt conceived was right. They established large cotton farms in several districts, particularly in Dharwar, and they sent out some gins, in the first instance, for the purpose of cleaning the cotton. After several years of this experiment, in 1835, instructions were sent out to abandon the cultivation of New Orleans cotton altogether, and, as far as the Company was concerned, we should thus have been hopelessly condemned to the indigenous cotton of that country. This did not, however, satisfy the manufacturers of Manchester, and they resolved to make another attempt, and, accordingly, they sent to the United States, and engaged a number of Americans to go out to India; at the head of them was placed a military officer, not practically acquainted with cotton matters, and many of the rest were equally incompetent. In the meantime the experiments to which Mr. Colburn had alluded were undertaken. He (Mr. Shaw) took little credit to himself in the matter, but he was the first person who introduced the New Orleans cotton into India as an experiment, and it succeeded. After the first year he applied to the Government for assistance in extending the cultivation of that quality of cotton, but it was refused, on the ground that all the previous experiments had failed, and that it was useless to give further aid to promote that which they were satisfied would not succeed. However, the experiments went on, and the cotton was pronounced to be as good as any grown in the United States, but it was found that the old saw gin was useless for cleaning that cotton; a number of saws were sent out by the Company, and fitted up in rude machines by native blacksmiths. The only appliance previously was the native churka, a very rough instrument, and the only wonder was that cotton could be cleaned with it at all, except that the black seed cotton was hard and smooth, and easy to separate from the seed, but when applied to green seed cotton the fibre was greatly bruised and damaged. It was, therefore, necessary that there should be great improvements made in the mode of cleaning cotton in India. If India was to compete successfully with the American States in the growth of cotton, a quality of cotton such as that grown at Dharwar must be introduced. It was incredible the number of applications that had been made to the Indian Board for assistance in relation to this object. The aid required was not of a pecuniary character, but merely that the Government should place in each cotton-growing district of India men who thoroughly understood the cultivation of that plant, and who could induce the natives to act upon the advice given them, so as to make the New Orleans cotton popular amongst them. The reply to deputations on this subject invariably was, "It is not the duty of the Government to interfere; go to India yourselves and grow cotton there." He submitted it was emphatically the duty of the Government to interfere in this matter. Seeing that they had given a guarantee of five per cent. to an enormous capital expended in carrying out railway communication to India, for the purpose of opening out the resources of that country, was it too much to call upon them to promote the growth of cotton there? He contended the Government had lost the greatest opportunity they ever had of competing with the American States in the cultivation of cotton; and when-

ever the war in America terminated, India would fall back, in respect of the cotton question, into the position which it occupied ten years ago; but, on the other hand, if what had been done in the Dharwar district had been done throughout India generally, England at the present moment would have been independent of America for her permanent supply of cotton.

Mr. JAMES GARSIDE trusted that the forebodings of the last speaker with respect to the cotton question in India would not be realised. He (Mr. Garside) took a more hopeful view of the case. There had been some confusion in the use of the term Surat cotton. The so-called Surat cotton was grown in Goozerat, which was the district from which they might look for the main cotton produce of India. The bad name acquired by that cotton he believed was mainly owing to its unscrupulous adulteration, but that was not the fault of the gin employed. In India they had the native gin, the American gin, and the gin combining the recent European improvements. There was another machine employed by the natives besides the churka, the work done by which was excellent, though the process was a slow one. One great want of India was an efficient churka or hand gin, so as to afford employment to the large surplus female population of towns in India. The cotton question was now entering upon an entirely new phase. Up to the present time the profits of the cotton cultivation of India had been derived by the native agents rather than by the growers; and there could be no question that for the last three years great advantages would have been gained in every respect if the English manufacturers had been brought into more immediate contact with the ryots, so as to buy the produce directly from them instead of through native agents. The real secret, with regard to the cotton question in India, was the obtaining of a fair remuneration by the growers for their produce, and a permanent and safe market for it. That could be effected by no better means than by the establishment of some half-dozen substantial farms by Englishmen in the principal cotton districts. There was no difficulty in dealing with the ryots; and in proportion as good faith was established between them and the buyers, and as they were assured that there was a safe and permanent market for their produce, so would be the increase in the extent of cotton cultivation. In speaking of the peculiar adaptability of the Goozerat district for the growth of cotton, Mr. Garside remarked that the prevalent belief was that a great portion of that district was the base of an ancient fresh-water lake, containing vast deposits of vegetable matter. Here cotton was grown without artificial irrigation. A still more important matter than the gin, with regard to India, was the proper selection of the soil. Without that they could never get good staples. Looking at the specimens in the India Museum, the cotton was of better quality 150 years ago than it was at the present time. Formerly, Surat was the Liverpool of India with regard to the cotton produce of the country. The Indian ryot only required the certainty of the English market to stimulate him to the production of large quantities of cotton; but whilst they had the melancholy prospect held out in the speeches and writings of such men as Mr. Cheetham and Mr. Ashworth, that it was useless to think of growing cotton in India for the permanent English market, they could not hope that the vast resources of that country would be employed to anything like an adequate extent in that direction.

Mr. BAZLEY, M.P., would divide the few observations he should offer on this subject into two points; first, the necessity of obtaining a good quality of cotton; and, secondly, the necessity of its being well prepared for the market. His friend Mr. Shaw had given the meeting an account of the origin of the growth of the superior cotton of the Dharwar district, but Mr. Colburn had inadvertently fallen into an error in supposing that the chief part of the cotton sent to this country from India was of the Dharwar class; that class constituted only about one-

teeth of the cotton that came from India. Of the great pre-emptiveness of that district in the cultivation of cotton, however, there could be no question. It would be, no doubt, a difficult task to overcome the prejudices of the natives in favour of the indigenous seed, and bring them to cultivate the superior quality of American seed, and in that respect undoubtedly good service had been rendered by the personal exertions and encouragement of Mr. Shaw. The native cotton dealers were in the first instance so prejudiced in favour of the indigenous produce, that it continued for a long time to command a better price at Bombay than the superior staple produced from the American seed; and it was not until the opinion of the English manufacturers was evinced by the larger price which the Dharwar cotton brought at Liverpool, that these prejudices were removed. It was gratifying to find that as the civilization of the people of India progressed under European government their long-retained prejudices were being rapidly removed. In no respect was this more apparent than in the matter of prejudice of caste. At the present day people of all castes travelled together in the railway carriages, where formerly they would not have been found in the same house together. It happened that the party of Americans Mr. Shaw had alluded to, as having gone out to India to improve the cotton cultivation, passed through Manchester, and he had the pleasure of showing them a fine crop of cotton plants, flowering, growing in an attic story of one of his large cotton mills. The production of cotton was not merely a question of seed, but also of soil and method of cultivation. The cotton plant required a loamy soil with an admixture of sand, with a looseness and moisture that would enable the roots to penetrate two feet into the ground. It was frequently planted on such hard soil that it could not obtain the necessary nutriment. A great many of the British colonies, such as portions of Australia, the West Indies, and some parts of our African possessions, were exceedingly well adapted for the production of large quantities of cotton. He thought it was a disgrace to us as manufacturers that we had allowed ourselves to remain so long dependent upon the slave-grown supplies of cotton from the States of America. About fourteen years ago, he had the honour of giving a lecture on this subject in that room, on which occasion the lamented Prince Consort did him the honour to preside, and he then called attention to the great danger of our reliance upon the fragile support of slave labour for our supply of this important staple. If the course indicated by Mr. Shaw had been pursued, no doubt by this time we should have been independent of the American States in this respect, and the amount of suffering which had been experienced in Lancashire would have been avoided. It was most important that the natives of India should understand that we want cotton of long fibre and sent to market in a well prepared state fit for the manufacturer's use. But the fact was the grower of cotton in India was not paid a price according to the quality of his produce. Good and bad qualities stood almost on the same footing; the cotton-grower therefore required to be taught the value of superiority of quality; and if he were made to understand that a higher price would be given for cotton of the staple of an inch than for that of a quarter of an inch, he would make efforts to supply that which was wanted. In all probability there would be a considerable reaction with regard to the cotton cultivation in India, upon the re-opening of the American supplies to this country, unless the system of cultivation in India was placed on a firmer and more satisfactory footing. He deplored the loss of opportunity by the Government of India in stimulating the production of the higher qualities of cotton at a time when the price of that article was so enormously high. Last year the amount of money transmitted to India by our manufacturers for the cotton produced there was, at the present high prices, so large that India was an important gainer by the transaction. If the price of cotton fell to its normal figure,

India would be the loser to a considerable amount; but if the cotton was of that high class it might have been made, the loss would be greatly diminished, as the price would be higher. He had seen cotton of every class from India, and he believed they might have from the most generally useful class, which was New Orleans, up to the finest Sea Island—all the produce of India—if proper efforts had been made to obtain the cotton we want. With respect to the cleaning of the cotton, unless the article was good in itself, no mechanical operation would ever make it fit for the manufacturer's use. The Indian churka had, probably, been in use nearly 2,000 years, and it was a singular fact that the finest samples of Sea Island cotton from the American States were prepared by the roller gin, which was a machine very much upon the principle of the ancient Indian churka. The Whitney gin was applicable to short staples only. The length of the New Orleans was on an average only about three quarters of an inch. It was not merely from the superior toughness of the New Orleans fibre that the saw gin did not injure it, but from the length of the staple, which permitted the teeth of the saw to pass over it without injury. The staple of Sea Island cotton was from $1\frac{1}{4}$ inch to 2 inches, and although the fabric was strong, yet if, owing to its length, it got into loops, the teeth of the saw tore these apart, and injured the staple to the extent, in his opinion, of 10 per cent., which, on a large crop of cotton, made a very serious item. For this reason he hoped to see the saw-gin superseded by the roller-gin. The Macarthy roller gin was brought into this country, a few years ago, under somewhat curious circumstances. Some Sea Island cotton was sent over prepared by this gin. It had a most beautiful fleecy appearance, almost like a mass of snow, and he (Mr. Bazley) was so pleased with the condition of this cotton, that he wrote to his agent, at Charleston, to send him one of these Macarthy gins. In due time it arrived, and he had a number of them made by merchants in different parts of Lancashire. The machine now before them was an offshoot of it. By the aid of that gin he had no doubt there would be great economy in the preparation of cotton for the spinner, and the yarn made from that cotton was in many respects superior in quality. Economy in the separation of the fibres was of great importance. If 5 per cent. of cotton were left on the seed it was a loss equivalent to the amount they paid for cleaning the cotton. This ought not to be in itself an expensive operation. A good saw gin would produce 2,000 lbs. of cotton a week, worked with wind or water, and attended by a couple of negroes. The Americans were very clever in the use of the saw gin, and by ingenious modifications they had reduced the amount of injury to the fibre to a minimum. They wanted skill applied to the cultivation of cotton, and good machinery for cleaning it. There was one difficulty referred to connected with the introduction of large quantities of Indian cotton into this country—viz., that the English manufacturer could not place himself in direct communication with the planters. In America a different state of things existed, owing to the large number of agents employed there, to whom the criticisms of the manufacturers were conveyed, and by them transmitted to the planters; so that the English spinner could, as it were, almost bespeak the precise nature of the article he required. A striking contrast in this respect existed in India. As manufacturers they had no knowledge whatever of the cultivation, but if they could have agents to stimulate the growers to produce better cotton, he believed the regeneration of cotton cultivation in India would be accomplished. He was more and more convinced that the proper stimulus to all exertion—viz., a due reward for it—was all that was required to produce results alike beneficial to this country and to India.

Mr. Buxton mentioned that in travelling through Syria and the Holy Land he was surprised to find what a large amount of really good cotton was spoilt by the use of a gin even worse than that employed by the Chinese.

Having described the construction of that machine, he added that he had seen thousands of them at work in Syria. The great outcry in that country was to get a proper machine for cleaning the cotton; but it appeared that no European had ever introduced any improvements upon the primitive method still employed there. With respect to any improvement in the quality of the cotton, he learnt that one grower had been induced to try a better kind of seed, which he planted in a small patch by the side of the native cotton. He was highly delighted with the result, and for a long time kept the fact of his having this new seed a secret. The inquiry consequent upon a better quality of cotton was naturally for a better machine to clean it with. Throughout the whole district of Lebanon, to the river Jordan and the Dead Sea, the growth of cotton had greatly increased, and from inquiries he made he ascertained that the produce last year was sixfold that of the preceding year. He was persuaded that considerable quantities of cotton might be obtained from Syria, if proper means were taken for that purpose. With regard to quality, he believed it was of a description that would generally meet the requirements of our manufacturers, and that it could be sold at 7d. per pound, to yield a profit of 30 per cent. to the grower.

The CHAIRMAN said he was sure the meeting would cordially agree in a vote of thanks to Mr. Colburn for his valuable paper.

The vote of thanks having been passed,

Mr. COLBURN, in acknowledging the compliment, said that although it was of the utmost importance to get a good supply of cotton, he regretted that on this occasion the discussion had tended almost entirely in this direction, and had not sufficiently referred to the best sort of gin for cleaning it. He thought, however, enough had been said by Mr. Bazley to show the importance of good ginning. Looking to the fact, as stated by that gentleman, that 10 per cent. of economy was gained by the Macarthy machine, which, on the average amount of cotton supplied to this country, would amount to no less than £8,000,000 per annum. The only difficulty with respect to that gin was the comparatively small amount of work it turned out, but he believed the new gin, to which attention had been called, did its work quite as well as the Macarthy, at the same time producing a larger quantity of work. It was, in fact, the Macarthy gin with considerable improvements, and he believed it accomplished nearly as much work as the saw gin.

A collection of various forms of cotton gin belonging to the Society was on the table, and at the conclusion of the discussion, Mr. Colburn showed the operation of the new gin referred to in his paper.

Proceedings of Institutions.

GLASGOW INSTITUTION.—The sixth annual report says that, although the directors cannot report an increase of students, there has been no decrease in the acquirements and progress of the students and scholars receiving instruction in the Institution. The numbers who attended each class during the year are as follows:—Mathematics, 26; free-hand drawing, painting, &c., 30; mechanical drawing, 33; practical mechanics, 21; Latin, 40; Greek, 12; French, 64; Gaelic, 5; grammar, composition, and logic (English history as exercises), 112; arithmetic and book-keeping, 141; writing, 29; geography, 4. Morning classes:—Arithmetic, book-keeping, &c., 23; phonography, 16; elocution and English literature, 38; music, 6. Elementary evening classes (males), 79; ditto, and domestic economy (females), 26; ditto, advanced (females), 19. Juvenile day classes, 223. Select day classes, 16. Advanced day classes:—Mathematics, French, Latin, book-keeping, &c., 13; free-hand drawing, 133; needle-work, 27. From 20 to 30 per cent. of the above attended two or more classes. The number on the evening-class

list was 623, on the juvenile day-class list 223. The total number, therefore, who have received instruction in the Institution during 1863-64 has been 846. The number of certificates and prizes awarded by the Society of Arts to students of this Institution during the last four years, show how meritorious has been the work of its students. Of the whole number who came forward only ten were rejected; indeed, the Institution stands among the first for having few rejected. During the same time the Local Board has awarded 274 certificates for qualifications in the various branches taught in the Institution—these are given instead of prizes. The directors earnestly impress upon the students the great value of whatever tests or attest their qualifications, especially the certificates of the Society of Arts. They are of opinion that, were the Society to authorise certain initials to candidates who pass a successful first-class examination in a stated number of branches, it would add greatly to the value of the certificates, and also be a more powerful stimulant to the acquirement of education. The financial statement for the past year shows that the class fees amounted to £308.

FRANCE AT THE DUBLIN EXHIBITION.

In all the more attractive and decorative classes of objects, there will be a fine display from France at the International Exhibition. The Emperor himself heads the list with a splendid collection of porcelains from Sevres, and tapestry from Gobelins and Beauvais. Promises have also been received from Barbedienne, of bronzes; Barbezat for iron-work, and Thenard for silver-work. Musical instruments will be exhibited by Alexandre, Saxe, and Herz; laces by Lefevre and Ferguson; silks by Berteaux, Brunet, Lecompti, and many others. Furniture and all the *articles de luxe*, for which Paris is the head-quarters, will be well represented. The French department of the Exhibition will be in one of the most advantageous parts of the building, and the exhibitors are sparing no expense to render this department attractive and ornamental.

Fine Arts.

EXHIBITION OF PORTRAIT MINIATURES.—The following minute has been issued by the Committee of Council on Education:—My Lords read a memorandum on a proposed Exhibition of Portrait Miniatures prepared by Mr. Samuel Redgrave, and consider it desirable that the proposal should be carried into effect. The Exhibition will be opened at the South Kensington Museum, on the 1st June, 1865, subject to the usual regulations of the Museum as respects loans of objects. Several noblemen and gentlemen are to be requested to give their aid as a committee to advise their lordships on the subject. Mr. Samuel Redgrave is to be requested to undertake the special charge of carrying out this minute. The following are the particulars of the proposed Exhibition:—1. The miniatures which formed a section of the Loan Collection in 1862, were objects of so much interest that it is proposed to give a further development to an exhibition of this art, in which English artists were the first to excel, and which, though now seldom practised, flourished in England for nearly three centuries. 2. The Loan Collection comprised chiefly the works of our early miniaturists, Hilliard, Isaac and Peter Oliver, and Cooper (which were endowed with an antiquarian interest), with a few by Cosway, R.A., and some other artists. But the object of a second collection, though not confined to the productions of English miniaturists, should especially be to make a representative exhibition of their works, identified with their, in so many instances, almost forgotten names. 3. In seeking the assistance of the collectors and possessors of miniature art, they should therefore be particularly solicited to state, as far as it is possible to do so

authentically—first, the name and titles of the person represented, and the date of the portrait; second, the Christian and surname of the artist; and third, the birth-place, date of birth and death (where not commonly known), with any other particulars that may prove of interest. A request should at the same time be made that such persons will kindly point out any other persons who possess miniatures which it is probable they will lend for exhibition. The collection might be completed so as to open some time in June next, and should include miniature portraits—first, in enamel; second, in oil and in water colours; third, in chalk or in pencil, whether drawn on vellum or paper, in plumbago solely, or in the latter manner with the face tinted. The following by no means extensive list, contains the names of many of the artists who practised in England, and whose works should be sought out and solicited for exhibition:—Miniaturists of the sixteenth century—Hans Holbein, John Bettes, Thos. Bettes, Nicholas Hilliard, and Isaac Oliver. Miniaturists of the seventeenth century—John Hoskyns, Peter Oliver, Samuel Cooper, Alexander Cooper, George White, Thos. Flatman, Alexander Brown, Thomas Sadler, Jean Petitot, William Faithorne, Sir Balthazar Gerbier, Richard Gibson (the dwarf), William Hassell, Sir R. Peake, Thomas Forster, Theodore Russell, Mary Beale, Penelope Rose, David Loggan, and Robert White. Miniaturists of the eighteenth century—John Dixon, Charles Boit, A. Plimer, Lewis Crosse, James Ant. Artaud, James Deacon, Bernard Lens, Thomas Frye, John Heens (of Norwich), William Blake, John Kitchingman, Thomas Worledge, John S. Liotard, Nathaniel Hone, R.A., John Caballiere, Charles Macourt, John Alefounder, Alexander Pope, Thomas Redmund, Samuel Finney, Francis Cotes, R.A., Charles Sherriff, Miss F. Reynolds, John Foldstone, Michael Moser, R.A., Luke Sullivan, John Jackson, R.A., Christopher Richter, Christian F. Zincke, Mary Benwell, Bernard Artaud, Jarvis Spencer, William Roth, John Platt, Edward Dayes, A.R.A., John Donaldson, Henry Spicer, and Ozias Humphrey. Miniaturists of the nineteenth century—James Nixon, A.R.A., Mary Moser (Mrs. Lloyd), Samuel Collins, Samuel Shelley, Richard Cosway, R.A., Maria Cosway, Charles Muse, Henry Bone, R.A., Andrew Robertson, Alfred E. Chalon, R.A., Sir William Ross, R.A., F. Chinnery, and artists now living. It is hoped that possessors of miniatures worthy of note, either on account of the person represented or of the artist by whom the portraits were executed, will by their contributions give as much completeness as possible to the proposed exhibition, which both from an historical and an artistic point of view will be one of very great interest.

Manufactures.

PAPER MATERIAL IN FRANCE.—According to the returns published by the Director of Customs, the following is the weight and value of the rags exported from France during the last five years:—1860, 3,662,323 kilogrammes, value 354,649*fr.*; 1861, 2,270,971 kilogrammes, value 1,249,934*fr.*; 1862, 4,161,265 kilogrammes, value 2,233,696*fr.*; 1863, 7,171,140 kilogrammes, value 3,040,579*fr.*; 1864, 8,010,715 kilogrammes, value 10,809,606*fr.* It might be presumed from these figures that France exported during the last two years a quantity of rags equivalent to 7 or 8 per cent. of the amount required by paper manufacturers at home, but such is not the fact. The Customs' returns comprise the drills, or woollen rags, which are not used in the manufacture of paper. When these are subtracted it will be found that the rags suited to paper manufactures exported in the year 1863 amounted to 2,877,801 kilogrammes, and the value to 453,901*fr.*; and in 1864 to 2,820,868 kilogrammes, value 429,912*fr.* The removal of the prohibition has not, consequently, deprived French papermakers of more than 3 per cent. of the rags they use. The French paper

manufacturers have now resolved to petition the Senate to recommend the abolition of all duty on the export of rags, provided all other nations in Europe would do the same. The papermakers are likewise agitating in a more practical manner. They have established depôts in the less affluent quarters of Paris, such as the 18th and 19th arrondissements, where rags are sorted and washed. Persons employed to collect rags for these depôts will prevent the destruction of an article hitherto so much despised.

FRENCH IRON MANUFACTURE.—In 1854 the quantity of pig iron made in France was 750,069 tons, of which 280,000 tons was charcoal-made. In 1863 the rate had increased to 1,180,000 tons, but the proportion of charcoal made was smaller, being only 280,000 tons.

VEGETABLE FLANNEL.—This fabric has for some time been in considerable demand on the Continent, and is used in place of ordinary flannel in the case of persons troubled with rheumatism and neuralgic pains, and of those especially whose skin will not bear the irritating action of woollen fibre. Vegetable flannel is a German manufacture, from the *Pinus Silvestris*. Its introduction is credited to M. Léopold Lairitz; and a large number of persons in the Black forests are now engaged in the various processes of separating the oil and the fibre, called *waldwoll*, or forest wool, from the pine leaves, and of spinning, weaving, and knitting the yarn. As regards the hygienic qualities of the vegetable flannel, Dr. Hoppe, of the University of Bâle, and other scientific men, rate them very highly. Baths of pine leaves have long been used in Germany and Switzerland in cases of rheumatic affection, and the vegetable flannel is believed, like the baths, to have an immense power in establishing the functions of the skin when they have been interfered with by accidental causes. This result is attributed to the presence of formic acid—which creates a gentle and constant excitement of the skin—and of the tannin and resinous principles which are absorbed by cutaneous action, and supply the necessary elements for restoring a healthy condition.

Commerce.

OSTRICH BREEDING.—The problem of the domestication of the ostrich in the temperate regions of Northern and Southern Africa, appears already to be attended with satisfactory results; and instead of chasing the bird from its destination, in order to obtain the valuable spoils of its plumage, it can be bred and led to yield its feathers periodically for the wants of fashion. Some few years ago, it was stated that great success had attended experiments at the Jardin d'Acclimatation, at Hamma, in Algeria, the director of that establishment having received the premium of £80 offered by M. Chagot, sen., feather florist, of Paris, a member of the Commission of Valuers to the French Ministry of Commerce, who was the first to get the ostrich to breed in a domestic state; and the reproduction promises to obtain for commerce the ostrich plumes, which are daily becoming more rare and dear. At a recent meeting of the Cape Agricultural Society, M. L. von Maltitz, well known as one of the most enterprising and successful farmers in the Colesberg district, gave a statement of his short experience in ostrich farming; and any theory formed as to the profits which might be realised by such a pursuit falls immeasurably short of the result obtained. M. von Maltitz said: "My desire is that a prize be given to the proprietor of the largest number of ostriches in the district. I believe I am at present the only owner of those birds, and, therefore, I may, in making the proposal, be suspected of interested motives. To set that at rest, if a prize be offered and awarded to me, I will return it to the Society, to be again competed for at the following show. My sole object in moving the resolution is to encourage ostrich farming in the district, by which I am convinced, by my own short experience, enormous profits may be realised. Towards

the close of last year, I purchased seventeen young ostriches of three or four months old. I placed them in an enclosure of 300 acres in extent, in which they had a free run. They have been kept there ever since, and have subsisted entirely upon the herbage of the enclosure, except an occasional feed of grain when driven up to the house for the inspection of visitors. I had at the same time other stock within the enclosure, and the opinion I have formed with reference to the extent of ground requisite for their grazing is that 35 birds can be carried year in and year out upon 300 acres of good grazing land—I mean land rather superior to the common run. At the end of last April I had the wings of the birds plucked, where the feathers of commerce grow. In consequence of the youth of the birds, these feathers then obtained were valueless. I now find, by recent examination, that the birds will be fit to pluck again at the end of the present month, verifying the statement made at the last Swellendam show by one of its members, who was, like myself, experimenting in this novel description of farming, that he obtained feathers fully grown from his ostriches every six months. My ostriches are so tame that they allow themselves to be handled and their plumage minutely examined. Being desirous of ascertaining the opinion of those versed in the trade, as to the commercial value of the feathers, I have had the birds examined by several, and the general opinion is that the largest feathers, of which there are twenty-four on the wing of each male bird, are worth £25 per lb., and that the yield of the whole plucking, the majority of the birds being males, will not fall short of £10 each upon the average. I think the statement made at the Swellendam Agricultural Show sets the value of each half-yearly plucking at £12 10s. per bird, and this, I have no doubt, will be the average of mine when they arrive at maturity, according to the present market value of feathers. The original cost of the young birds was about £5 each." In the last Cape papers it is stated that only a few small parcels of ostrich feathers had come to hand during the month, and for those offered at public auction competition had been very keen. All descriptions realised extreme prices, the best being sold as high as £27 10s. to £30 10s. per lb. In 1862 there was imported into the United Kingdom, chiefly from South Africa, Morocco, and France, 38,142 lbs. of ostrich feathers, valued at £76,256.

MEXICAN MINERALS.—Mexico is proverbially a mine of wealth, and one that has, in proportion to its richness, been but little worked. The new regime has given a great impulse to the search for available minerals, and a new find is announced almost every week: M. Rodriguez Soza has opened up a petroleum well at Hacienda de Santa Anna, in the province of Ernango; M. Ventura Alcerreca has found a white marble quarry in a small hill called Pescuay, in the province of Zumpango de la Laguna; and M. Hecfonse Lopez a deposit of bitumen in the department of Oajaca, near Port Angel, another to the north of Pochutla, a third on the bank of a stream called Cruz, and a fourth between Port Angel and the sea. Further, a new deposit of coal has been found near the village of San-Pedro, in the gorge of San-Andres, in the province of Ecatepec.

Colonies.

AUSTRALIAN GOLD.—The quantity of gold dust imported into the Sydney branch of the Royal Mint, for the purpose of coinage, from the 1st of January to the 14th of October last, amounted to 599,228 ozs., and the coin issued was 2,225,000 sovereigns. For the same period of the year 1863 the receipts of gold dust amounted to 371,366 ozs., and the coin issued was 881,000 sovereigns and 556,500 half-sovereigns. Total value, £1,169,260. The increase in the business of the Mint is solely caused by the large quantities of gold received from Melbourne

for coinage, and is not to be attributed to any improvement in the yield of the gold-fields. The following table will show the total amounts received and issued from the 1st of January to the 30th of September, 1863 and 1864, and the weekly receipts from that date to the 14th of October, 1863 and 1864:—

	1863.	Sova.	Half-sova.	Ozs.
January to Sept. 30 ...	845,000	556,500	354,869	
October 7	16,000	—	3,457	
" 14	20,000	—	18,040	
	881,000	556,500	371,366	
1864.				
January to Sept. 30 ...	2,186,000	—	570,645

TASMANIAN STATISTICS.—The population of the colony, by the census of 1861, was 89,973. The acres in cultivation in the whole colony, in 1863, were 267,173; of these, 139,321 are in the railway district. The value of the crops of 1863, in the whole colony, as given by the Colonial Secretary, was £934,915; the value of the crop, of the district, £427,430. The value of the live stock of the colony, in 1863, as published by the same functionary was £1,478,011, and of the railway district, £493,238. The annual value of the landed property of the colony, taken from the assessment rolls for 1864, was £675,000, representing a capital sum of £11,250,000, whilst the same property in the railway district was assessed at £287,187, representing, therefore, a capital sum of £39,531,000. During the four years ending December, 1863, it appears the excess of the imports over the exports, at Hobart Town, amounted to ££412,907; at Launceston, the excess was, of exports over imports, £416,409—a substantial proof of the commercial requirements of the northern districts, in regard to roads and improved means of locomotion. The yearly average of the customs' revenue collected during the same period was, at Hobart Town, £68,288; and at Launceston, £56,048; whilst the expenditure for civil service, exclusive of public works, has amounted to £105,900 per annum at Hobart Town, against £19,900 per annum at Launceston. The Crown lands sold in the railway district (with Devon) during five years ending December, 1862, amounted to 149,242 acres, for £194,416.

EMIGRATION.—During the past year there have been despatched, by the Emigration Commissioners, 30 ships with Government emigrants to Australia, and four to Natal. Of the Australian ships ten sailed for New South Wales, eight for South Australia, two for Victoria, seven for Queensland, and three for Western Australia. Seven ships were despatched from London, three from Southampton, seventeen from Plymouth, and seven from Liverpool. The passage money ranged from £12 10s. 6d. to £15 9s. 3d. per statute adult, and averaged, for Natal, £12 18s. 10d.; for Queensland, £13 1s. 4d.; for New South Wales, £13 3s. 4d.; for South Australia, £13 4s.; for Victoria, £14 1s. 11d.; for Western Australia, £14 5s.

NEW SOUTH WALES.—EXPORTS AND IMPORTS.—The exports from New South Wales for the year 1863 were valued at £6,936,839. The imports were valued at £8,319,576, showing an excess of £1,372,637. Rather more than half the imports came from Great Britain. From the colonies, produce to the value of £2,672,069 was imported, and from foreign countries to the value of £1,106,022. More than six-sevenths of the trade, therefore, in this respect was carried on within the limits of the British Empire. Of the exports England received £2,287,357, the colonies £4,459,101, and foreign states £109,381. The reason why exports to the other colonies figure so high, is, that the export to Ceylon, consisting mainly of gold, was valued at £1,906,983, and the exports to Queensland amounted to £1,070,895, which in-

cludes the exports re-exported coastwise. Next to the United Kingdom the highest imports are from Victoria, and these also represent an intercolonial trade. Queensland comes next in the list; then South Australia, from which breadstuffs are received. Of foreign countries, Manila received the largest sum of money for sugar and cigars; next came China for tea, and next the United States for a variety of commodities. There is very little sold to these foreign countries in return. The live stock imported seaward into the colony was valued at £20,176. The live stock exported seaward was valued at £109,821. This latter branch of business was more flourishing than in any previous year, and was due to the demand that sprang up in New Zealand. Preserved meat was imported to the value of £38,503, and exported to the value of £35,649. The imports of 1863 fell below those of the previous year by a little more than a million sterling, but they were above those of any previous year by nearly as much. The exports fell below those of the previous year by about £160,000, but they were above those of any year previous to 1862. The whole course of trade, therefore, of the year, exhibited some signs of slackness. The most decaying branch of trade was with the fisheries, the imports from which amounted only to £9,431, while in the previous year they reached £27,608, and in 1856 were as high as £39,020. The total value of the export of wool was £1,828,000, which was a higher amount than had been reached in any previous year. The export of tallow was valued at £31,221, which was only about a third of that of the previous year. The timber import was valued at £88,832, and the export at £42,190. The value of the coal exported was £220,181, and the quantity was 296,038 tons. Both in value and quantity this was somewhat below the standard of the previous year.

QUEENSLAND CYPRESS PINE.—Among the other timber products of this district may be mentioned the tree called cypress pine. Of a peculiarly fine and handsome grain, it promises to supply the want much felt there of timber suitable for household furniture, sashes, doors, and interior fittings of houses, while its scent is reported as equal to anything in rose or sandal wood. The tree, which has usually a tall, straight stem, averages a foot in diameter, and splits readily for either slabs or shingles. Few persons appear as yet aware of the existence of this tree, the nearest stock at present known being over twenty miles from Clermont, in the direction of Peak Vale. It is hoped, however, that in the event of cypress pine possessing the properties attributed to it, its proximity may soon be turned to profitable account.

QUEENSLAND SUGAR.—Some very excellent sugar has been grown and manufactured at the Victorian Cotton Company's plantation. It is said to be worth £40 per ton.

Obituary.

MR. HENRY BLUNDELL, of Hull, died January 29th, 1865, aged 75. Born in 1789, and educated at Lincoln, he crossed the Humber, and after an apprenticeship with the late Mr. William Thomas, in Church-street, Hull, he commenced business there in 1810, and founded a branch of the colour trade in that town, which is at present represented in every important capital in Europe, and fast extending over the world. Under his management the "green" paint manufactured at the establishment has attained such celebrity that the name of the maker is almost invariably associated with the colour. In another branch of trade in which he was engaged—that of seed crushing—Mr. Blundell was the means of effecting improvements of a most important and enterprising character, which have conducted in no small degree to the prosperity of Hull. He applied hydraulic pressure to seed crushing, and was mainly instrumental in raising the machinery to its present state of perfection; the strongest testimony to the soundness of the principles by

which he was actuated consists in the universal application of hydraulic power in the trade of which he was the most prominent member. As a man of business Mr. Blundell was universally respected; his liberality and promptitude earned for him the esteem of all men, and the respect of the 300 workmen who were permanently dependent upon him for support. Mr. Blundell had worked long and arduously as a public man; and was one of the oldest, if not the oldest, magistrate of the borough. He fulfilled the duties of the mayoralty in 1852, when the British Association visited Hull, and many members present at that scientific congress still retain pleasing reminiscences of his kindness and hospitality. Mr. Blundell's presence in the Town Council was instrumental in producing several important reforms. An ardent sanitary reformer, he devoted every effort to the amelioration of the social position of the working classes. To his energetic advocacy of the scheme, the public is indebted for the establishment of the baths and washhouses. Of the Infirmary and other local charities he was a liberal supporter. As chairman of the South Bridge Company, he has taken an active part in promoting a project which is likely to prove one of the most important local improvements of recent years. In the rifle corps, too, Mr. Blundell evinced great interest, and presented a valuable prize for competition during last season. He was elected a member of the Society of Arts in 1853.

EUGÈNE DEVÉRIA, with his brother Achille (who died in 1857), once occupied a very prominent position in the artistic world of Paris. He had, however, lived for many years at Pau, but was struck down suddenly on revisiting the city of his birth, at the age of sixty years. His best known works are:—"The Birth of Henri IV.," in the gallery of the Luxembourg, which fixed his reputation; "The Reading of the Sentence on Mary Queen of Scots;" "The Death of Jeanne D'Arc;" "The Battle of La Marais," in the Versailles gallery; "The Inauguration of the Statue of Henri IV. at Pau, in 1846;" "The Death of Jane Seymour;" "The Four Henris;" and "Reception of Columbus by Ferdinand and Isabella," painted in 1861. He also painted a great number of portraits, amongst which are those of the Marshals Brissac and Crèvecœur, at Versailles. He also executed a ceiling in the Louvre, the subject being Louis XIV. and Puget; and the Chapel of St. Geneviève, in the Church of Notre Dame de Lorette. The brothers Devéria were at one time the leaders of the romantic school. The halls given in their ateliers were the most famous in Paris, and scenes which took place there have been delineated by more than one pencil. All the literary and artistic youth of the period appeared there in coats of mail, satin *justaucorps*, and every imaginable form of knightly, troubadour, and fancy costume. A celebrated art-critic of the present day is spoken of as once resplendent there in the character of Charles IX., and another in the bizarre dress of a poor scholar of Cluny in the olden time. From the atelier of the Devéria are said to have sprung the pointed hat, which, mounted above a luxuriant mass of hair dressed in the style of the Merovingian period, sent young Paris mad about the year 1830. This style of wearing the hair was called *La Perinet Leclerc*, and it was succeeded by another, entirely different, the almost shaved head, then named *coiffure à la mal content*, and later *au forêt*. In or about 1836 these eccentricities almost entirely disappeared, and the once famous leader of the romantic world, Eugène Devéria, retired to Pau, and became a Protestant clergyman, and was famous for the rapid, picturesque, and effective style of his oratory.

ALEXANDER FRASER, A.R.S.A., died on the 15th Feb., at his residence, Wood-green, Hornsey, in the 79th year of his age. He was born in Edinburgh, on the 7th April, 1786. He studied at the Trustees Academy, where he, Sir David Wilkie, Sir William Allan, Sir John Watson Gordon, and David Roberts, were fellow-students under John Graham. With the two last named he had pre-

viously worked in the employ of Bengo, the Edinburgh house painter, before they became fellow-students. He then came to London, and commenced his profession as an artist. His pictures in the public exhibitions gained favourable notice. He became Wilkie's assistant, and during twenty years worked in his studio, mostly on the still-life details of Wilkie's pictures. During this period he was frequently able to exhibit original works of his own at the Royal Academy and British Institution, at which last exhibition he obtained the premium for the best picture of the year, with his "Naaman cured of the Leprosy." This success was followed by his being made Associate of the Royal Scottish Academy, of which he had been one of the founders, and by other honours tendered by his townsmen. Commissions from some of the best patrons of the day followed, and he soon occupied a distinguished position as a painter of *genre* subjects. His principal works were:—"Robinson Crusoe explaining the Bible to Friday," painted in 1836; and the "Interior of a Highland Cottage," painted for Mr. Vernon, and now at South Kensington. The subjects he chose were chiefly Scottish.

Publications Issued.

EUGENE DELACROIX.—*FAC-SIMILE DE DESSINS ET CAQUIS ORIGINAUX*. Par Alfred Robaut. Printed at Douai.—A remarkable work, both as regards subject matter and execution. M. Robaut has well rendered the sketches of Delacroix, and his lithographic copies are as near fac-similes as possible. Not only are the strokes and touches given precisely as in the original, with here and there the notes of the artist attached, but the various colours and tints of black, white, and red chalk, sepia, pen-and-ink, and pencil, are reproduced with strict fidelity. The work is also well printed. The sketches are on folio paper, and the two series which have appeared at present, include more than fifty sketches, or rather sheets, for in some cases there are more than one sketch on a sheet. Each sheet may also be purchased separately, at from two to four francs. The genius of Delacroix is so remarkable in his original sketches that these bear a higher value in proportion to his finished works than is usually the case. His daring male figures frequently call to mind some of those of Michael Angelo. Moreover, many of the sketches are the originals of ceiling decorations, which cannot be photographed, and are, in fact, much superior, in a purely artistic view, than the finished works.

Notes.

PORTUGUESE INTERNATIONAL EXHIBITION.—This Exhibition of Arts, Manufactures, and Agriculture, inaugurated by the Oporto Crystal Palace Company, is under the patronage of his Majesty Don Luis I. and the presidency of Don Fernando of Saxe Cobourg Gotha. It opens on the 21st August, and is to close on the 30th December. From the 6th to the 15th there will also be, in connection with it, an Agricultural Show of Plants and Animals. Medals and certificates of merit are to be awarded. Mr. Alfredo Allen is the Secretary at Oporto, and Messrs. W. H. Ivens and Son, Colonial Agents, Crutched-Friars, are the agents for the Oporto Crystal Palace Company in London, and will take charge of and forward goods, and represent parties there.

EXHIBITION AT NICE.—A universal exposition of Horticulture, Industrial Culture, Acclimatation, and Scientific Collections, is to be held at Nice, about the 1st of May. Artistic and industrial productions will also be received. Articles may be sold at the close of the Exhibition. The Emperor gives two medals of honour—one to the foreigner or Frenchman who most con-

tributes to the splendour of the Exhibition, and another to the inhabitant of the department (Alpes Maritimes) who does the same. The Empress of the French, the ladies of Nice, the Grand Duchess Helen of Russia, the Prince of Morocco, and Prince Oscar of Sweden, also offer prizes.

DOG SHOW IN PARIS.—A dog show is to be held in the avenue of the Cours la Reine, in the Champs Elysees, near the Palais de l'Industrie, from the 9th to the 14th of May next, under the direction of the Zoological Society. Persons wishing to send dogs are required to make known their intention by a post-paid letter to the Director of the Zoological Society in the Bois de Boulogne, previous to the 17th April. The letter is to contain the number, the breed, and the age of the animals proposed to be exhibited.

COD FISHERIES.—From the official returns relative to the French ships engaged in the cod fishery in the North Sea during the year 1864, it appears that the number of cod fish taken in 1864 was less than that in 1863—the weight in 1863 being 2,240,000 kilogrammes, and in 1864 only 2,048,000 kilogrammes. On the other hand, the take of flat fish was double in 1864 to that of 1863. There was likewise a very remarkable increase in the quantity of seal oil brought home. It amounted to only 16,000 kilogrammes in 1863, and increased to 112,000 in kilogrammes in 1864.

LOCUSTS IN SENEGAL.—The plague of these creatures has been fearful this season in the above-named country. Their ravages have been terrible, trees being stripped of the whole of their leaves, and shrubs and small plants being utterly destroyed. The total loss in the case of the cotton plant, which has escaped lightly, is estimated at three-fifths of the crop. In the experimental nursery grounds of the Taouey the cotton plants have been completely destroyed; not a leaf is left. To give some idea of the countless numbers of these insects, it is said that on the 19th of November last the steam dispatch-boat *Archimède* was moored opposite the nursery ground above mentioned, with the Governor on board, when a most extraordinary spectacle presented itself. A cloud of locusts, following the course of the left bank of the Senegal river from west and east, completely hid the land from view, like a thick curtain. The insects flew at the rate of about four miles an hour, and were passing from dawn till sunset, thus forming, as it were, a column from thirty to forty miles long; but, as at sunset the cloud towards the west was much more dense than at any other period, the inference was that what had gone by was merely the *avant-garde*. The unfortunate cultivators are in a state of despair, while the Moors, who do not trouble themselves with agriculture, console themselves by capturing immense quantities of the locusts, which they declare to be, if not the most agreeable, at any rate the most wholesome food that can possibly be imagined. It is the converse of the old proverb, "What is one man's meat is another man's poison," or, at any rate, destruction. The locusts eat up the poor farmer's crops, and the Moors eat up the locusts, or, at any rate, a few millions of them.

SUPPLY OF WATER TO PARIS.—Few cities were worse supplied with water than Paris not many years since, and still the mode of supplying is primitive, dear, and inconvenient. There is no such thing in Paris, in the ordinary way, as a huge cistern or butt from which the pail may be replenished *ad libitum*. Great reforms are, however, being made in this matter; a water company is gradually carrying its pipes into private houses, and the common sewer is growing rapidly in size. The means taken for increasing the supply are grand, both in conception and extent; aqueducts, canals, and artesian wells are being excavated and constructed in all quarters of the outskirts. One reservoir at Menilmontant, which is rapidly approaching completion, has two stages, and is destined to contain 100,000 cubic metres of water, at the height of 108 metres above the level of the sea, and 35,000 cubic metres in the other compartment at 100 metres altitude.

At Belleville is another reservoir, also half finished; this is also divided into two parts, one to hold 15,000 cubic metres, at the height of more than 134 metres, and the other 25,000 cubic metres, at an altitude of 131 metres. At present one of the upper compartments is filled with Seine water raised by machinery at Charonne. The aqueduct for bringing the waters of the Dhuie to Paris is being carried on with great vigour; in the year 1863 sixteen kilometres of canal and syphons were executed; last year ninety-six kilometres; and only sixteen or eighteen kilometres more remain to be accomplished, which it is expected will be done by the month of May. No work of the kind was perhaps ever performed more rapidly. Immense works are going on at Saint Maur for supplying a portion of the reservoirs and the lakes of the Bois de Vincennes; the subterranean conduits are terminated, the foundations for the machinery laid, and the buildings in hand. The lakes are expected to be supplied by these means with water from the Marne in May, and the supply of Paris with the same a month or two later. Two new artesian wells are being sunk; one of these has unfortunately fallen on a stratum of fine sand fifty-six feet thick, which has created great additional trouble, while the other has met with no serious difficulties, and is already finished down to the chalk deposits. In connection with these important works it will be interesting to give the price at which filtered water is sold by the municipal authorities to the water carriers, or other people who choose to be their own aquarii. According to a decree of the Prefect of the Seine, the price is 10 centimes for a hectolitre and a half, rather less than a penny for upwards of thirty-three gallons, and for a painful one centime, or the tenth part of a penny. This decree came in force on the first of February.

Correspondence.

CANTOR LECTURES.—WATER-SUPPLY FROM WELLS.—**SIR**,—I am much obliged to Mr. Homersham for his notes of the quantity of water supplied from wells in chalk and new red sandstones. Few engineers are better qualified to give such information. In my lecture, and in the abstract published in the *Journal*, I rather pointed out the quantity that might be anticipated from such rocks under ordinary conditions than the exceptionally large quantities yielded by particular wells. I believe I mentioned that such exceptions occurred. Allow me to take this opportunity of correcting an error in the abstract in the second paragraph of Lecture II., referring to the water-contents of sand. In the second column of page 218, line four, the word "ten" should have been *ex*; and in line eight, for "ten," read *seventeen*.—I am, &c.,
D. T. ANSTED.

Athenum Club, March 6.

VOLUNTEER FIRE BRIGADES.—**SIR**,—Mr. W. Roberts, in his letter which appeared in the *Journal of the Society of Arts* for the 3rd instant, "regrets to see his friend Mr. Young" getting into the track of underrating "the services of the regular brigade." Now, I beg to assure Mr. Roberts that I am not doing anything of the kind; that I fully appreciate the services of the regulars, give them every commendation for their exertions, and every credit for all they do; but I still maintain that they are perfectly insufficient for the work which is now required; that we have no right to ask or expect them to do it; and that we are doing wrong to leave the work to be done by those who have no obligation to perform it. As to his remarks respecting trained men, Deal boatmen, soldiers, life-boats, &c., there is no necessity for a reply to them, for we know what has been done by less likely volunteers than these; but I still say, and it is constantly proved by facts, that far greater results have been, are, and will be, achieved by volunteers than by any paid men whatever; and if he says paid services are best, surely he cannot feel that he is acting in

accordance with his convictions by commending and encouraging the services of a volunteer and unpaid brigade.—I am, &c.,
CHAS. F. T. YOUNG, C.E.
7, Duke-street, Adelphi, W.C., March 7th, 1865.

TAKING FISH BY SUBMARINE ILLUMINATION.—**SIR**,—On Wednesday, the 1st inst., I attended, by invitation, at the Society of Arts, to hear a paper on the above subject. The attendance was good, and the paper interesting. I was, however, much surprised at remarks that fell from the Chairman (Sir E. Belcher); and this feeling, I think, was general, from what I heard around me. The chairman opened his address by proclaiming the prejudices that he had against our fishermen making good seamen, from their liability to be sea-sick, &c. He then proceeded to relate his own surprising success as a fisherman, but could not be prevailed upon to explain the secret of it. The admiral's ideas were evidently those of the old school. I must, however, demur to his law, when he remarked that Mr. Fanshawe's patent "was of no value, as three miles out at sea it could be used with impunity." As well might the admiral say the same of Trotman's anchors, or any other patented marine invention. Probably the admiral also forgot that, unlike his own long cruises, fishing-vessels must, of necessity, frequently return to port; and the owners of those using Mr. Fanshawe's invention without his license would probably find it expensive to rely on the admiral's law with regard to patent right.—I am, &c., J. C. STOVIN.

Patents.

From Commissioners of Patents Journal, March 3rd.

GRANTS OF PROVISIONAL PROTECTION.

Artificial stone, manufacture of—441—W. Kirrage.
Beam engines—468—J. G. Jones.
Boats, ships, &c., apparatus for propelling—365—M. Bier.
Books, trimming the edges of—324—W. H. and F. C. W. Latham.
Boots and shoes, manufacture of—291—A. Murray.
Boots and shoes, manufacture of—442—R. A. Brooman.
Bricks, clay for the manufacture of—452—R. Hill and E. Tushingham.
Bricks, making and pressing—480—C. W. Homer.
Casks, lifting and tilting—446—C. O. Staunton.
China and earthenware, ornamenting—435—F. J. Emery.
Collisions at sea, prevention of—445—H. C. and J. Cleaver.
Cylinders, apparatus for lubricating—466—T. Ogden.
Drinking cup, invalid or syphon—437—R. H. Emerson.
Envelopes, apparatus for folding—479—J. D. Nichol.
Envelopes, fastener for—495—H. F. Ribton.
Fibrous materials, preparing—376—E. Lord.
Fibrous materials, spinning and carding—90—R. Tempest.
Filters—467—R. A. Brooman.
Fire-arms, breech-loading, cartridge boxes for—254—E. Blakeslee.
Fire-arms, revolving—308—S. W. Wood.
Glass, ornamented articles of—497—T. G. Webb.
Hats, apparatus for ventilating—498—J. Carter.
Highways, &c., machine for clearing, sweeping, &c.—444—H. J. Plcard.
Illusory exhibitions, apparatus for—222—J. H. Pepper and T. W. Tobin.
Iron, manufacture of—470—W. Robinson.
Iron or steel chains, making the links of—422—G. Homfray.
Iron safes and strong rooms—499—G. N. Shore.
Ladies' stays, lacing and fastening—361—C. Field.
Leather, composition as a substitute for—465—C. Brakell, W. Hoehli, and W. Gunther.
Leather, &c., machinery for sewing—484—C. Baulch.
Lime, preparation of superphosphate of—320—W. E. Newton.
Liquids, measuring the specific gravity of—448—J. F. Hearnay.

Magnesium, manufacture of—456—J. O. Christian, and J. and H. Charlton.

Ordinance, breech-loading—372—A. Krupp.
Oralic acid—449—F. A. Laurent, J. Cathelais, and N. Basset.
Pen and pencil holders—394—E. J. Hill.
Potash and soda, sulphates and carbonates of—460—C. F. Clans.
Railway carriages, &c., electro-magnetism as a break power to—161—F. Barnes, D. Hancock, and E. Cowpe.
Railway carriages, signalling by the passengers to the guard of—290—E. Whittaker.
Railway passengers, &c., apparatus for the protection of—472—L. W. G. Rowe and A. Saab.
Railway passengers, securing the safety of—454—C. Desfries.
Railway rails—434—D. C. Pierce.
Railway signalling, electro-magnetic apparatus for—463—C. V. and A. O. Walker.
Railway trains, communication between passengers and guards, by night or by day—289—J. W. Gray.
Railway trains in motion, shifting points on—474—G. H. H. Ware.
Railway trains, machinery for stopping—487—E. Jesumun.
Roadways, pavements, &c., construction of—335—C. Henderson.
Safes—450—J. Thompson.
Saab fasteners—482—W. Hitchin.
Scarfs—491—I. Pariente.
Sewage, treatment of—451—R. Smith.
Sewing machines—478—H. Percy.
Solid substances, extracting liquid from—486—W. E. Newton.
Steam engines—166—W. C. Hicks.
Steam engines—486—J. R. Swann.
Steam ploughing—366—R. Winder.
Stopping bottles—414—W. C. Hine.
Valve, balanced slide—496—W. E. Newton.
Vessels of war, armour plates for—455—J. Brown.
Volatile liquids, apparatus for distilling—447—W. E. Newton.
Water, boilers for heating—493—J. Hulley.
Working ships' pumps—303—M. Blank.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

Paper collars—566—S. S. Gray.
Rifle, magazine repeating and breech-loading—540—E. H. Eldredge.
Vehicle for teaching children to walk—637—J. Askew.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MARCH 22.—"On the Preservation of Food, especially Fresh Meat and Fish, and the best form for Import and Provisioning Armies, Ships, and Expeditions." By G. C. STARR, Esq.

MARCH 29.—"On Window Horticulture, and the Cultivation of Plants and Flowers in Cities and Crowded Localities." By JOHN BELL, Esq.

CANTOR LECTURES.

The Third Course for the present Session will consist of six Lectures "On Some of the Most Important Chemical Discoveries made within the last Two Years," to be delivered by Dr. F. F. GRACE CALVERT, F.R.S., F.C.S. (Corresponding Member of the Royal Academy of Turin; of the Société Industrielle de Mulhouse; of the Société Imperiale de Pharmacie de Paris, &c.), on Tuesday evenings, at Eight o'clock, as follows:—

APRIL 4TH.—LECTURE 1.—On the discoveries in Chemistry applied to Arts and Manufactures.

APRIL 18TH.—LECTURE 2.—On the Discoveries in Chemistry applied to Arts and Manufactures (*continued*).

APRIL 25TH.—LECTURE 3.—On the Discoveries in Agricultural Chemistry.

MAY 2ND.—LECTURE 4.—On the Discoveries in Physiological Chemistry.

MAY 9TH.—LECTURE 5.—On the Discoveries in the Chemistry of Rocks and Minerals.

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

MUSICAL EDUCATION.

The Committee appointed by the Council to inquire into the present state of Musical Educa-

tion at home and abroad, consists of the following gentlemen:—

Wm. Hawes, Esq., Chairman of Council.

Lord Henry Gordon Lennox, M.P.

Lord Gerald Fitzgerald.

Sir John P. Boileau, Bart.

Sir George Clerk, Bart.

Sir John Harington, Bart.

Sir Francis Sandford.

Colonel Scott, R.E.

Capt. Donnelly, R.E.

Edgar A. Bowring, Esq., C.B.

Harry Chester, Esq.

Henry Cole, Esq., C.B.

Herbert Fisher, Esq.

Samuel Redgrave, Esq.

His Royal Highness the Prince of Wales, President of the Society, has consented to honour the Committee by acting as its chairman.

Proceedings of the Society.

CANTOR LECTURES.

SECOND COURSE.—SIXTH LECTURE.—MONDAY, MAR. 13.

MINERAL VEINS, ORES, AND MINING.

Professor ANSTED commenced by stating that the last division of his subject included mineral veins, their contents, and the methods adopted to extract these contents. Metals are obtained either native or as crystalline minerals, called ores, from certain fissures and veins in altered rocks. The obtaining of ores from veins is metal mining. All rocks now above the water have been raised to their present position by some powerful upheaving force. They must have been dried before being elevated, and this involves contraction. Contraction and elevation must have produced cracks and fractures, whose nature depends partly on the rock itself, and partly on the mode of action of the moving force. It is not possible to conceive upheavals without fissures; but they are of two kinds, as due to two causes. Those caused by contraction will be governed by chemical laws. Those caused by upheaval will be regulated by the amount of force exerted, the weight to be lifted, the direction of the upheaving force, and the mechanical condition of the rock at the time of up-

heaval. The first kind may have begun as soon as the rock existed. The second kind commenced with the first upheaval. They may be due to a multitude of movements going on for a long time. During long periods such fissures may have remained unaltered. From time to time they may have been interfered with by other fissures. But cracks once formed, and then neglected, may have been filled up with fragments of the adjacent rock, or with crystals that have grown in the cavity. A crack in a mass of limestone may be occupied with calc spar. A wide fissure in such rock may be filled with rolled blocks of limestone. An empty space may have become filled with lumps of zinc or lead ore. All rocks present phenomena that have some resemblance to those of mineral veins; the formation is an ordinary event in nature. Crevices formed during the elaboration of a rock, are small, and filled up with crystalline material derived from the rock itself. The rock is purged of foreign contents by aid of these cracks, and by the facilities they offer for throwing off substances of which there is only a small proportion. But the filling up of crevices formed by contraction need not differ from the filling of wider cracks. The crevice must be formed before the filling up can begin, and thus every true crack must have defined walls. This distinguishes true veins from differences of condition and of mineral composition which belong to some process of segregation. The successive veins in slates and granites, elvans, bands in clays, and coloured lines and marks in sandstones, are of this nature. They are modifications of the rock, but not mineral veins. Of the two classes of fissures those produced during the formation of the rock are the simpler and the most common. All fissures in rocks, filled with crystalline minerals may be called mineral veins, but only those which contain valuable ores are lodes or metalliferous veins. The origin of the vein is of small importance, but its history is interesting, and will guide the miner in following the traces of the vein when it is lost sight of. Metalliferous veins in stratified rocks are chiefly confined to accumulations of lead and zinc ore and carbonate of iron in natural open spaces or caverns in limestone. It is difficult to explain this, but it is a law of nature, at least with certain limitations. Let us see what these veins are like, and what clue we can obtain to their history. Between and amongst limestones, where the bedding is regular, and cavities occur at the interval between two beds, there may be deposits of galena and calamine. These cavities communicate with others by crevices across and between the strata. How far the natural cracks may have been enlarged by subsequent upheaval, it is impossible to say, but the main deposits of ore often seem dependent on the stratification. There is little guide to the discovery of veins of this kind when lost, beyond a careful following of the clue afforded by a thread of ore. Useful mineral veins are the result of disturbances that are systematic, and they often correspond with the structure of the part of the country where they occur. Thus, in Cornwall and Devon there is a chain of granite bosses ranging east and west, and a quantity of slates, schists, &c., having a similar range. In the slates, schists, and granite are numerous metalliferous veins. Of these some are more regular, and better defined than the rest. Such veins are called master lodes or champion lodes. They are parallel to each other, and may be recognized as belonging to a system. These main lodes range in the same direction as the axis of elevation of the district. The general range of the local geological axis of the country being made out, then the direction of the main lodes are parallel to it, and the lodes of next importance at right angles to it. And this law is an expression of the fact that mineral veins are fissures in altered rocks, produced systematically by mechanical force elevating the whole district, and breaking up the rocks in a manner that may be estimated mathematically. If a rigid solid, tied down on all sides, be exposed to pressure from below, sufficient to overcome the tension of its parts, it must crack

on yielding, and these cracks will follow certain law. They must be parallel and at right angles to each other and to the elevating force. One important conclusion from this mode of considering mineral veins is, that in different countries the systems of veins must exhibit different directions. Thus, while the ore-bearing veins in Cornwall are east and west, in other districts they may be north and south. The direction of elevation must govern the formation of each system of veins. But if veins are due to disturbances that have acted at intervals during a long period of time, and not always in the same direction, the axis of disturbing forces may change, and there may be new systems of veins crossing older systems. Or successive elevations may produce complication in a different way, breaking up and heaving the mineral veins after they have been filled. Thus are produced faults and throws. In the determination of the law that governs the distribution of lodes, we should know the direction of the axes of elevation that have effected them, and the order of the occurrence of the disturbance. The fissures formed in rocks, whether on solidifying or whilst elevation was going on, must approximate rather to a vertical than horizontal direction. Thus mineral veins are often almost vertical, or if inclined they are so slightly and irregularly. But fissures in rocks are not lodes until they have been filled with mineral matters. These are usually crystalline. The filling up distinguishes the mineral vein from the open fault, or crevice, and the lode from the mineral vein. There is no reason why a fissure open at the top, or a crack formed during the construction of an ordinary fault, should not become filled with stones from above or from the walls. Occasionally the vein contains substances washed in by water from a distance. But when mineral veins are filled with spar the case is different. The material may have been carried in from above and deposited from water. In this way some veins in limestone contained in a solid mass angular and rolled lumps of limestone, galena, blende, calamine, and shells. The cementing medium is carbonate of lime, and the agent water. So it is possible that crevices open below have received minerals in the state of vapour. Of these sulphur and arsenic are familiar examples. The former is found lining the walls of cavities. In volcanic districts examples of this are common. Thus deposits from above, brought in with or without water, and deposits from below, with or without steam, are methods adopted by nature. But no one familiar with veins will suppose that all known cases can be thus explained. The vast majority of lodes are lined with crystalline minerals which have commenced to form on each wall of the vein, and not either at the top or lower part. When the deposit has begun, the crystals have accumulated symmetrically. Assuming that crevices have become converted into veins by chemical action within the rock, this either involves the conveyance of foreign material by water circulating through the veins, or the passage of this foreign material through the mass of the rock itself. Both are possible. Water circulates through all free spaces in the interior of the earth. It is often hot, and loaded with a variety of minerals. Hot water no doubt has been largely concerned in bringing various ores as well as early minerals into veins. The filling up of veins is a subject of the deepest interest to the miner. He would willingly discover a law by which he could convince himself of the existence of ore from the nature of the surrounding rocks, or from the surface appearance of the lode, or from the intersections of lodes with each other, or with some particular kind of rock; or from the degree of inclination of the lode. Such laws are not known, and it will be long before observations on these conditions justify absolute conclusions. But there is some relation between the contents of a lode and the conditions under which it has become filled. By observing facts, and studying their mutual relations, miners have found that a gossan or iron oxide at the top of a lode is an indication of a course of ore. The condition of the gossan is significant.

some iron stones being recognized as favourable and some unfavourable. A "kindly gossan" is to a Cornish miner an indication of a valuable lode. So the fact that in lodes crossing each other, or in lodes traversing both granite and slate, there is generally a deposit of ore either at the intersection of two lodes, or at the point where a lode passing out of one rock enters another, must be regarded as tolerably well established. Little is known of the cause of this result. It may have been due to an electric or galvanic action, or it may have reference to causes altogether distinct. The study of the observations illustrating this rule cannot fail to be useful; but we are met by the difficulty of assigning a satisfactory reason for a phenomenon certainly very common. The condition of the enclosing rock is not without influence on the contents of a lode. An experienced miner will judge by reference to this of the value of an unworked vein. Certain conditions of softness in slate and granite are considered favourable, but a compact rock rarely contains large quantities of valuable ore. This applies to quantity rather than quality. Less important is the inclination of a lode. The valuable lodes of a mining district have certain mutual relations, but there is no clear identification of the cause. Certain metals and ores are common in lodes having one general direction, while other ores belong to other rocks and to cross courses. This is the case in all mining districts. In Cornwall the copper and tin lodes are usually in the direction of the axis of elevation, and are far the richest in ore; the lead veins are in the cross-courses, and are less important. In other districts, where the lead ores are in the main line of upheaval, the copper ores are of small amount, and occur in the transverse fissures. Mineral veins contain native metals, oxides, sulphides, or carbonates. Other combinations are less common and less abundant. All these are found in veins mixed with quartz, with crystalline salts of lime, and with clay, in large quantities. It is in mineral veins that the larger proportion of those combinations occur that seem to have little importance on the earth's crust, but that must certainly have uses and influence. Few metals and ores are sought with much care. The chief are, iron oxides and carbonates, iron pyrites, native copper, oxides, sulphides, and carbonates of copper, oxide of tin, sulphide and carbonate of lead and zinc, sulphide and oxide of silver, native gold and silver, native mercury, and sulphide of mercury. The metals and minerals of which the supply and nature are such that they are unknown in the general market are not here referred to. All ores are not found in abundance in the same district, in the same kind of rock, or in the same kind of vein. Certain laws exist, in obedience to which they may be looked for, and these laws must be ascertained by observation. What is true for Cornwall is true in principle, but not in detail, for Wales, for Chili, for Cuba, and Australia; and if the experience acquired in Cornwall is taken abroad, and there applied without consideration of the change of circumstances in the deposits, it will fail. Mineral veins containing ore are of very various dimensions. Of their length little is known. They are traceable in some cases for many miles at the surface, and below the surface they probably run on for far greater distances. It is difficult to say what is the inferior limit of length, for pipe veins and shoots are often in sets, and connected by narrow crevices. The width is more determinable than the length, and varies from a few inches to many yards. A silver vein in Mexico exceeds fifty yards, though not for any great distance. The width is sometimes increased by parallel fissures filled with ore, and threads of ore pervading the rock that encloses the vein. This condition of veins is a stockwerk, and lateral veins are called also strings. The depth to which mineral veins bear useful deposits of ore is unknown. Tin and gold have been supposed to abound near the tops of lodes more than at great depths but this is not likely. The tops of lodes often consist chiefly of quartz and iron oxide where the lode con-

tains a large quantity of iron, with or without copper or other metals, and where the vein stone is siliceous. Veins in granite and slate are vertical or nearly so, and the same system of lodes generally shows the same underlie. In limestone they are often zigzag, mere gaps of small depth, or open spaces between certain beds of limestone and shale. There are certain associations of earthy minerals with metal. The sulphides of copper are generally accompanied by siliceous minerals. Rich ores of silver are often found in gneiss, with quartz, while silver-lead ores and galena are abundant in limestones. These general indications of habitat are useful, but they cannot be trusted in all cases. Owing to the nature of mineral veins and lodes, their hardness always differs from that of the enclosing rock. If harder, they stand out above the surface as walls; if softer, the top of the lode is more rapidly weathered than the walls, leaving a depression. In either case the lode is broken away, and carried along the surface by water. When left behind the heavier portions containing the ore will be accumulated in certain places, but in smaller quantities and smaller particles, as they are more distant from the lode. By following up from point to point the traces of a lode from these fragments, a miner will discover the position of the lode. This is called shodding. When a lode is reached it is necessary to prove its direction and underlie, its width, and its condition at various points of outcrop. For this purpose trenches are cut across the direction of the lode at certain points where it ought to be. These are called costeaning pits. These are generally the best means of discovery, without the outlay of much money and labour, and the lapse of a long period of time. Mining is speculative; and of all kinds of mining that which is most elementary, namely, the discovery of valuable lodes is the most speculative. At one time a trial and the expenditure of a few hundred pounds will lay bare a deposit of enormous value; at another, the utmost prudence and intelligence, with capital, will end in failure. Lead and zinc deposits in limestone are different from veins in granite and slate, and the search for lead is thus different from that adopted in reference to copper. Lead deposits are irregular, and the process of shodding adopted on the surface with regard to copper, is applicable underground for lead. In some lead districts, where the ore is found between bands of limestone, this method is applicable; Derbyshire is an example in point. It is not so in Flintshire and the Isle of Man, which are also lead-mining districts. Mining districts are to some extent indicated in a good geological map. They occur where rocks have been metamorphosed; where granites and slates and schistose rocks are found; where granite appears; where the contact of granite with sandy and clayey material is marked by changes in sands and clays, and where limestone is disturbed, we may look for fissures systematically grouped, and containing crystalline minerals and ores. The more remarkable of such districts are those in England, Cornwall and Devon. Derbyshire, Northumberland, and Cumberland are the chief mining counties for metalliferous ores in mineral veins. North Wales supplies lead and copper, and the Isle of Man is rich in silver-lead ore. In North Wales gold has been found. Ireland contains copper mines. Scotland contains lodes in its south-western counties. France presents five metalliferous districts. Belgium is rich in zinc and lead. Spain is exceedingly rich in most of the metals. Italy is very rich in iron and copper. Germany was the cradle and is the school of scientific mining, and the variety of minerals found there is very great. Silver, copper, lead, tin, cobalt, nickel, bismuth, antimony, and iron are all found there, and some under circumstances of extreme interest. Scandinavia abounds in iron and copper. In Russia there are many mining districts, and silver and lead are worked in the Altai mountains. Throughout Asia mining districts are known to exist; and the islands of the Southern Archipelago, as well as Australia, contain important supplies of useful metals. Both North and South America

are metalliferous, and Central America still yields the chief supplies of silver. The native copper on the shores of Lake Superior is one of the most remarkable deposits in the world. When a lode is known to exist, and the indications justify operations, it is usual to sink a pit on it or cut it by a level or adit driven in from the nearest hill-side. If ore is found it may be run out from such an adit, and if water comes in it may be drained without cost from all workings above the point at which the adit cuts the lode. Assuming that the lode improves on going down, and justifies a farther outlay, a shaft is put down to cut it at some convenient point. At various depths cross-cuts may be made towards the lode to prove its position and the state of the ground and of the ore. All lodes are in their nature irregular. They contain what are called courses of ore, or they are bunched and contain pockets of ore. The former condition is that of a deposit of ore uniform within certain limits of depth and distance, succeeded by barren portions. Experience has too often proved that there is no dependence to be placed on the presumed continuance of courses of ore in any direction. Bunches and pockets of ore consist of expansions of a lode filled with ore, or portions of a large lode exceptionally rich. Courses of ore occur not unfrequently in the great copper mines of Cornwall. Pockets of ore are most common in the lead-mining districts. Mining work includes—first, the removal of ore already discovered; secondly, the laying out, and bringing into a convenient state for extraction, the courses and bunches of ore already discovered; and, thirdly, the organising of trials and discoveries in those parts of the lode not yet proved to bear ore. Judgment is needed in laying out a mine so as to secure a supply of ore to pay expenses, retaining a reserve in the event of the supply failing, and expending a fair proportion of the profits in trial work. Owing to the irregularity of lodes, shafts must be put down to suit the condition of the lode. Thus slant shafts are sunk either from the surface or from some point below, and, by perpetually following the ore and removing it wherever there is sufficient to make it profitable, the works become extremely complicated. It is impossible to carry on mining operations on a large scale in mineral veins without timbering. When the vein is nearly vertical, it requires little timbering to prevent the walls from coming together, especially when the country is solid, and the walls clearly defined. But there are cases where the excavations are so large as to render timbering a very costly operation. Sometimes the waters of the mine tend to rot the timbers that are used to shore up walls, and keep the overhanging wall from closing in on the foot-wall. There is no objection to the use of gunpowder in blasting in metal mines. Judgment is needed in deciding on the position and depth of the bore-holes, to take advantage of natural joints in the rock, and remove large blocks. The plan of a metal mine is rarely systematic. But there is always one leading idea based on the method of removal of the water, and connecting this with discovery. Where the rainfall is large, the water that accumulates in a deep mine may become very considerable, as it comes in from above, from the sides where the lode connects with small branches and strings, and from below. It must be removed at the smallest possible cost; but, unless care is taken, the water lifted from one mine may find its way down another, or require to be lifted over and over again from the same workings. To avoid this, systematic drainage of groups of mines is desirable, and deep adits are cut, which receive the waters of a number of properties and convey them to a distance. In Cornwall the great adit receives the waters of the numerous mines in Gwennap and Redruth districts, and measures thirty miles in length. One branch penetrates ground seventy fathoms below the surface. The water thus conveyed is discharged into the sea forty feet above high-water mark. In the construction of long lines of deep adit, it is desirable to cross at right angles the direction of the principal lodes of the district. Metal mines are reached by ladders placed vertically in the

shafts, but when the depth is great the descent and ascent become extremely exhausting, and waste time as well as strength. Of late years, man-engines have been adopted, by means of which the men can reach their work and leave it with comparative comfort. Man-engines are not needed for shallow mines, and would not be advantageous where the depth is less than 200 fathoms; below this the gain is very great. Almost all the mining work in Cornwall is executed by contract. There are two classes—the “tutmen,” who excavate at a price per fathom of ground, and the “tributers,” who speculate on ore ground when reached. Poor mines are worked by tut-work, but when good ore is reached the tutman engages to raise it at a certain price per fathom. In other cases the tributers come in and speculate. They agree to work a portion of the lode for a given time, receiving a certain agreed portion of the ores raised. If the ore be rich, they accept a small percentage of the value, if poor, they demand a larger percentage. The captains, having decided the value to the best of their judgment, put up a portion or *pitch* to auction, the bidding being downwards, and the parties who bid being each represented by one man. The ores are generally raised by machinery and broken at the surface. In addition to the quantity of rubbish left below there is thus generally a waste heap, or *atle*, at the pit-mouth. This is produced during the operation of *dressing*. Professor Ansted then gave a brief recapitulation of the general subject, and concluded with the following remarks:—Thus it is that geology, applied to the arts, is a subject of real and vital interest to all of us. In endeavouring to illustrate this, and interest you in the subject, I have confined myself as much as possible to familiar facts and exemplifications. I need not point out to you that to follow these generalisations into detail one must possess a very wide range of knowledge and great practical experience. These can rarely be combined in one person; and thus the agriculturist, the engineer, the miner, and the manufacturer must each learn his own department of practical geology, and apply it to his own purposes. The search after this knowledge is as interesting as the knowledge itself is useful; and the interest is increased when the student, before seeking out that which belongs to his own department, will make himself master of so much of the general subject as to see the bearings of theoretical views on all the details that come before him. There are other applications of geology that I have not brought under your notice in these lectures. Among them I would especially point out its application to the fine arts. I mention it now to remind you that the subject of applied geology is far from being exhausted; that, in fact, I have only considered it in one aspect, and that the many-sided science that deals with the earth, its history, its structure, its grand physical features, and the causes that have produced and are daily modifying them, is no less calculated to interest the artist and the poet than the farmer and the manufacturer. There is no limit to the study when we engage in the comparison of the works of Nature with their application to the requirements of man, and the operations of man's intellect.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 15th, 1865; Thomas B. Winter, Esq., in the chair.

The following candidates were proposed for election as members of the Society:—

Brandt, F. C. W., 3, Abchurch Chambers, Abchurch-lane, E.C.

Drake, Francis, Friar-lane, Leicester.

Jacobs, Lewis, 146, Strand, W.C.

Kiel, George Middleton, 16, Stanley-gardens, W.

Oakes, William Smith, Addison-road, Kensington, W.

Simes, N. Phillips, 58, Coleman-street, E.C.

Strachan, Mrs., Norfolk-house, Arundel-square, N.
Wilkin, Frederick, 10, Spring-gardens, S.W.]

The following candidates were balloted for and duly elected members of the Society:—

Dibley, George, 72, Malden-road, Haverstock-hill, N.W.
Miles, Henry Thompson, 61, Strand, W.C.
Redman, Capt. Gabriel J., 6, Belsize-park, Hampstead, N.W.

The Paper read was—

ON MARINE ENGINES FROM 1851 TO THE PRESENT TIME.

By N. P. Buxton, Esq., Engineer.

The history of the origin of the marine engine, and its slow advance, has been so often written, that I feel assured I shall not cause much disappointment if I pass over that already worn-out subject. I propose, therefore, to introduce to your notice the marine engine as it was in 1851, and the improvements which have taken place from that period to the present time. As the present paper alludes to the year 1851, it will not be deemed out of place to describe briefly the marine engines shown in the Exhibition of that date. The screw-propeller was then making but slow progress, consequently the attention of our engineers was diverted from straining their talents to produce more perfect arrangements. The following examples of marine engines were exhibited:

For the paddle-wheel, the engines were arranged as follows:—Vertical, angular or inclined, direct-acting, and oscillating; for the screw-propeller, a more varied and numerous collection was given, comprising disc, rotary; for horizontal direct-acting types, were the following, double piston-rod, return connecting-rod, trunk; after which, annular cylinder, vertical direct-acting, inclined direct-acting, single piston-rod; and, lastly, a beam engine. The largest pair of engines were 700 horse power collectively, horizontal, direct-acting, single piston-rod. The trunk engines were 60 horse-power collectively; these two examples were adapted for the screw. For paddle-wheels, the engines of the greatest power were a pair of 140 horse-power, of Belgian repute, the framing and paddle-centres being of wrought-iron, thus ensuring sufficient strength with a reduction of material and weight. To describe each engine in detail would be tedious, as well as of little value to the engineer of the present day. Allusion to the defects and improvements will be found under the different descriptions of the necessary appendages.

I will now proceed with a brief notice of the marine engines exhibited in the year 1862, when it will be seen that a great improvement had taken place between the two dates alluded to. We are, I am happy to state, still making an advance, and I trust to be able this evening to describe these improvements; but, at the same time, I beg to suggest that there is plenty of room for further improvement in the detail of marine engines, which, doubtless, will be ere long taken into consideration by those interested in these matters.

In the year 1862, our International Exhibition was again held, and with much success as far as regards marine engines. The class exhibited showed great improvement, both in design and arrangement. The oscillating engines adapted for the paddle-wheel did not exhibit much alteration, although it cannot but be said that in detail a change for the better was perceptible. With reference to the engine adapted for the screw, a complete revolution had taken place since the Exhibition of 1851. Valves and gear were altered, starting gear simplified; positions of condensers, air pumps and valves, in a much more correct state; number of details lessened; and, in fact, the entire arrangement fast approaching to a nearer state of perfection, viz., accessibility to all the

parts in action without disarrangement. The following is a brief account of the writer's observation of the class of marine engines exhibited:—The paddle engines were vertical and inclined, oscillating, of the ordinary type and arrangement. The valve gear was of two kinds—the counter-balanced eccentric, and the ordinary link motion. The air pumps were worked by eccentrics in some instances, and in others by cranks. The mode of starting was by the ordinary ratchet or wheel and pinion—the bilge and feed pumps were, in some cases, worked by the oscillation of the cylinder, and in others by separate eccentrics. The means for disconnecting were of the disc and the drag-link kinds. Paddle-wheels were exhibited with fixed and feathering floats. Five examples of oscillating engines were exhibited, including models and drawings. The engines for the screw propeller were as follows:—One pair of double trunk engines, having injection condensers with an improved arrangement of air-pumps and valves. The double piston-rod return connecting-rod type was well represented; this arrangement is used on account of the great length of stroke and connecting-rod attainable in a given space. In the Exhibition now alluded to there were six pairs of engines of this class, with injection condensers and air-pumps of the ordinary arrangement, and one pair of engines with the improved arrangement of condensers, pumps, and valves. The single piston type of engine was not largely represented—one pair with the improved injection condenser, pumps, and valves, and one pair with those of the ordinary kind. The single trunk arrangement was represented by one pair, with single-acting trunk air-pumps in the condensers. The air-pump trunk with double piston-rod return connecting-rod engine was shown by drawings only. Vertical direct-acting engines were represented thus—one pair with annular cylinders, double piston-rod, and injection condensers of the ordinary kind; one pair with single piston-rod and surface condensers; and another pair as the last, with ordinary condensers.

It will be understood that in the previous examples the cylinders were arranged in pairs, the cranks being at right angles. In order to obviate the strains imposed at the extremity of each stroke, one firm exhibited engines with three cylinders, with spur gearing for reversing, stopping, &c., which were termed the expansive and economical principle. Lastly, I allude to the writer's invention "Burgh and Cowan's patent antifriction trunk engine," so arranged, that the friction of the trunks is dispensed with, and no area lost in the cylinder. This arrangement was represented by a pair of engines and drawings. Having thus briefly alluded to the marine engines exhibited in the two International Exhibitions of 1851 and 1862, I will now proceed to give a detailed description of each portion.

The arrangement of marine engines in the hold of the ship is, perhaps, not generally thought to be of so much importance as it really is. It should be strictly understood that the attention required for engines of river steamers bears no comparison with that required for marine engines; imagine a ship in a gale, and heated bearings, and a faint idea can be formed of the duties required, and the reason for a free access to all the working parts.

For the purpose of illustration to those present, not professional engineers, I will briefly specify what the necessary component parts of a pair of marine engines of the present day consist of, viz., cylinders, pistons, slide valves, piston rods, slide casings, expansion valves, blow-through valves, piston rod guides, connecting rods, cross-heads, main frames, crank-shaft, eccentrics, rods, links, valve rods, guides, condensers, air-pumps and valves, injection valves, snifting valves, discharge valves, bilge and feed-pumps, valves for the same, starting gear, and turning gear, lubricators, and all the necessary levers, bolts, nuts, &c. It will thus be seen that marine engineers have more difficulties to contend with than is generally known. To understand the use and real character of each of the above details is not the work

of weeks or months, but years. It should not be forgotten either, that the honour of our nation, and the lives of its representatives, are often in the hands of the marine engineer. I will now proceed with the descriptive illustration of details, showing defects, improvements, and suggestions for the future, commencing with slide valves.

These valves govern the entrance and exhaust of the steam to and from the cylinders. Two kinds or classes of valves are now universally used, the common and the equilibrium; the former is so well known that a description of it is scarcely necessary. I will only observe that its use for larger engines is much on the decrease, on account of the stroke of the valve being due to its outside lap, which for large ports is considerable. Equilibrium valves are so called from the equal action of the steam tending to lift the valve from, as well as to press it on its facing. These valves are double-ported to reduce the stroke. One firm has lately introduced three-ported valves, to still further reduce the stroke. In order to reduce the friction of the valves on the facings, rings are used encircling the body of the valve, adjustment being gained by screws, ratchets, and springs to prevent looseness. In some cases a communication from the back of the valve to the condenser is arranged, to still further reduce the pressure on the valve facing. Slide rods are usually one to each valve, but latterly two have been introduced for large valves, which no doubt greatly assist in guiding the valve during its action.

The next portion in rotation will be that for working, reversing, and stopping the action of the slide valve, universally known as the "valve-link motion." The date of the origin of this motion is doubtful. Mr. Zerah Colburn, in his new work on locomotive engineering, tells us, however, that 1832 is the earliest period of its application for locomotives. Marine engineers introduced it firstly for oscillating paddle-wheel engines; afterwards for fixed, horizontal, and vertical engines adapted for the screw propeller. The object of the link motion is to reverse the action of the slide valve without disconnection. The links now in use are of two kinds—slotted and solid. The slotted link has the sliding block within it, whereas that of the solid kind slides within the block. The means adopted for raising and lowering the link are various. One maker prefers to use a lever, secured on a weigh-shaft, passing over the front part of the cylinders, motion being given by a worm and wheel, the former being keyed on or forming part of the starting wheel shaft. Another firm deems it better to impart motion to the lever by a ratchet and pinions. A third authority raises and lowers the link by a rod connected to a block surrounding a coarsely-pitched screw, motion being given to the screw by mitre gearing; whilst another firm prefers to fix the block, with the screw to be elevated and lowered. These two last are undoubtedly the most powerful of the examples given.

The systems at present adopted for guiding the slide valve rod are of three kinds. First, the dove-tailed guide, similar to that used by tool-makers for the arm of a shaping machine. Secondly, a block of gun metal sliding on two fixed turned rods as guides over and under the valve rod. Thirdly, the valve rod secured to a square bar, working in a bracket, and cap to correspond. This last may be said to be the most simple, but perhaps not so rigid as the first example. The double guides are complicated, but at the same time produce the rigid resistance to the strains imposed on the valve rod by the vibration of the link.

Some makers of marine engines prefer to allow the link to rest or hang on the block pin inserted in the lever of the slide rod weigh-shaft. Such a practice dispenses with guides. Excessive vibration of the link on or in its block greatly deteriorates the action of the valve, it being understood that whilst the link has an ascending or descending motion, as well as sliding, the strain on the valve rod is increased, and at the same time the stroke is effected. The excess of the vibratory motion is painfully perceptible

in the ordinary slotted link; the eccentric rods being connected beyond the block pin, a direct-action cannot ensue. The distance between the centres of the eccentric rods and block regulates the amount of indirect action. Links of this kind are often hung from a rod connected in the centre to the link, either to the clip or at the back. This is far better than at the lower end, as the connection of the suspension rod regulates the ascending and descending motion of the link whilst at work. The link resting on the block when for going a-head, obviates to a certain extent some of the evils alluded to. The gain by the introduction of the solid link, with the eccentric rods connected at its extremities, is strength with less material, but the vibrating motion is not decreased. In order to obtain a more direct, and, if possible, a perfect action, the eccentric rods have been secured to the link, so that the centre of connection may be on that of the block, and by this the vibratory motion is effectually got rid of. There have been two distinct modes for accomplishing this, which I have had the opportunity of observing. The first example is—two solid links, one on each side of the block, the eccentric rods being connected to pins on the outer face of each link, the inner face and sides being sustained in a groove in the block, which oscillates on its axis, in the eye of the valve rod, the links being one on each side. The second example is like the first in principle, but one solid link only is used, of a dove-tailed form in section, at the inner face, to prevent the link from slipping out of the groove in the block; the eccentric pins are fixed in the extremities of the link, and the rods are attached as in the last example, but with a single eye. The writer has designed a solid link and connection, which, although not superior in principle of action to the two last examples, is more simple in construction, and has less working portions; therefore it may be held to be worthy of introduction. A solid bar of iron is slotted at each end, to receive the single eye of each eccentric rod, so that the entire surface of the link remains unbroken; it is secured in a block with an adjusting portion and key at the back, the front being open sufficiently to admit of the ascent and descent of the eccentric rods; adjustment in front can be attained by loose portions and set-screws, but this last is not imperative, as the wear of the link and block is very slight when the acting eccentric rod is on the centre of the block; the block has provisions on each side for suspension, the valve rod having portions formed to receive the block; the back part of the rod works in a dove-tailed guide of the ordinary kind.

It now becomes necessary to treat of the suspension or lifting rods for solid links; for this a few words will suffice. As the ascent and descent of the link whilst in motion are governed by the length and position of the rod, it is almost needless to state that the suspension rod should be connected in the centre of the connection of the eccentric rod. The link, when for going a-head, should be down. It may now be argued that the vibration of the link, when for going astern, must be excessive. Granted; but as the forward motion of the ship is of the most importance, it is not unfavourable to economy to adopt the connection alluded to. In some cases the solid link is guided at the top or bottom, but this is only required when an overhanging or outside connection of the eccentric rods is resorted to.

The next portion for consideration is the expansion valve and gear; the use of this valve is to allow the steam to be cut off at the early or given part of the stroke of the piston, and the expansion or elasticity of the steam completes the power required. Now it is certain that the use of high pressure steam for large cylinders and short strokes, produces excessive shocks at the commencement of the strokes, and thereby entails an increase of strength in the materials used, so that the proportions are larger than when for ordinary purposes. It is clear also that, when steam is admitted at an excessive pressure against the piston suddenly, it (the piston)

receives an impetus equivalent to the power imposed, and in no case whatever could an engine of proportions for low pressure resist the strains imposed by the use of high pressure steam. The ordinary pressure adopted by marine engineers is from 20 to 30 lbs. per square inch, more often the former than the latter. I am not aware, however, of any cause why 60 to 80 lbs. should not be adopted, with a great increase of economy and power. Of course the present proportions of engines and boilers would have to be increased, if the same materials were used, but steel boilers, shafts, and rods might be introduced with considerable advantage, embracing great strength with less weight.

Having alluded to the ordinary pressures at present used, it will be well now to advert to the expansion valves. These valves are of three kinds—throttle, slide, and tubular.

The motions imparted to the throttle valve are oscillating and revolving, the latter is now most generally adopted, but with this disadvantage, that the action is equal both for supply and cutting off.

The slide valves are of the ordinary and gridiron type, the latter may be said to be the better, on account of the stroke being so short in comparison to that of the former.

Tubular valves are tubes inserted in each other, with ports to correspond, a sliding or rotary motion accomplishing the desired effect. The motions imparted to these several valves are generally uniform, either by mitre gearing or eccentrics, consequently the action of the valves is not perfect. The proper motion for an expansion valve is to open gradually and close suddenly; to obtain this the old but correctly working cam must be resorted to; this useful arrangement is too often discarded to make place for newer but less correct productions. It may of course be urged that the cam is not applicable for high velocities, but undoubtedly its use might be attained by introducing stiff gear and perfect equilibrium double beat valves; by dividing this valve centrally a more correct action can be attained, in relation to that of the steam, on the valve whilst closed and open. The merits and demerits of the expansion valves here alluded to are almost equal. The ordinary throttle-valve has less friction than any yet introduced, but it possesses the great evil of throttling the steam when closing; also when this valve is worked by levers, or has a vibratory motion, should the stroke be lessened, the full area cannot be attained. The last evil is dispensed with in the remaining example, as the ports or openings are much larger than required when the valve is at full stroke, and not too small when the least motion is given. The friction of the gridiron iron valve is perhaps in excess of the other examples, as in the case of the tubular valves the action of the steam is neutralized. The means adopted for altering the grades of expansion valves whilst in motion are various. A spiral motion is the one universally adopted, and there is not the least doubt it is correct.

I will now call attention to the following description of an expansion valve and gear which I have designed for high velocities:—A cylindrical casing has within it projections at given positions; two of these projections act as spaces between the ports of ordinary tubular valves. The valve now explained is tubular, but the area centrally is half of that of the ends, which are parallel for given lengths, due to the stroke of the valve. These parallel lengths also regulate the neutrality of the valve whilst in action. At the present time the means adopted to impart the motion is a disc of metal with a circular slot; within this slot is a brass nut into which is screwed a pin. The connecting rod of the valve is attached to the pin in the ordinary manner. The means for altering the grades of expansion is by loosening the pin by its handle, and allowing the nut to slide in the slot to the required position. It is almost needless to add that the steam enters at the side of the casing, and escapes around and through the valve, keeping it in equilibrium.

The valves next in requisition are those for the ends of

the cylinder, commonly known as relief valves. The usual kinds adopted are discs, with springs or weights to resist the given pressure of the steam. The action of these valves is, of course, due to the excess of pressure within the cylinder over that of the resistance caused by the springs or weights. It has been proved that in the case of excessive priming of the boilers the cylinders are suddenly flooded; in order to release the water, cocks are sometimes used, but in many instances the springs or weights are lifted by levers. Now, in the case of cocks, if not provided with valves beyond them they must be worked by hand at each return stroke of the engine, or the vacuum will be destroyed. The spring valves will close naturally, or by the spring on its release from the hand lever. High-pressure steam has been lately introduced, with great advantage, in the place of springs, but with an entirely differently arranged valve and casing.

I have arranged a relief valve, so that the spring is not tampered with by levers or hand power, and an instantaneous opening can be effected without cocks, &c. The spring valve has an opening in it centrally to receive on its outer side a flat disc, termed the vacuum valve. On the inner side is a provision mitred to receive a solid disc valve, which, on being pressed inwards by a spindle and lever, allows a free exit for the steam and water; on a vacuum being caused the vacuum valve, which is guided on the spindle alluded to, closes the opening air-tight; by this it will be understood that the spring has not been in requisition, but on closing the inner disc the spring valve becomes one of the ordinary kind. Previously to starting the engines it is well known a vacuum should be caused in the condensers, also the cylinders and slide casings should be warmed, and the condensed water be allowed to escape through the relief valves or cocks.

The valves used for the purpose alluded to are termed the "blow-through valves." It may be here observed that, in some cases, the ordinary plug cock is preferred for this purpose. When valves are introduced, they are generally of the ordinary disc kind, but one firm adopts a common slide valve for the purpose, with the advantage of simplicity of levers, &c., and easy manipulation.

The piston-rods of marine engines are subject to excessive strain; consequently, the use of guides is imperative. For the single piston-rod engine, the universal system is a channel underneath the rod, the guide-block being generally of gun metal, and the upper portion attached to the piston-rod by bolts and nuts. For double piston-rod engines, the guides are of two kinds: the first arrangement is as the last, and the second, as for high-pressure engines, or double guides. To say which is the preferable mode of arrangement of guides will, perhaps, be deemed bold, but I may venture to state that I deem that for the single piston-rod the best of any yet introduced.

I cannot close this portion of the present paper without alluding to the admirable arrangement for tightening the gland of the piston rod stuffing-boxes, introduced by the firm of Messrs. Maudslay, Sons, and Field. The screws are of the ordinary kind, but, in the place of nuts, worm wheels are used, worms being fitted to correspond; and motion can be given by a box-spanner while the engines are at work. This is one of the most important improvements tending to accelerate the progress of a ship during a voyage, say three or four months. Imagine the engines requiring stoppage during a gale in order to tighten the glands, and a fair estimation can be formed of the value of the improvement alluded to.

Having commented, though somewhat briefly, on the cylinder appendages, attention may now be given to the main frames and crank-shaft. The main frames may be said to undergo a continuous strain, and must, consequently, be of a certain strength in order to preserve the requisite rigidity. The cylinder is attached to the one end, and the condenser at the other, whilst the crank-shaft has to be supported in its bearings. Not many years ago a celebrated firm used to make the condenser and main frame in one casting: since that, we have had the well-known

frame like the letter A laid on its side, also the hollow frame, with a raised projection for the crank-shaft, and a stay from the upper portion connected to the cylinder; this last may be said to be the most simple, and, at the same time, of less material than the A frame. As before stated, the strains on the frames are continuous, yet, when sudden shocks occur, from the racing of the engines or priming of the boilers, the tenacity of the cast-iron is severely tested. As this is the case, wrought-iron might be used with great advantage, both as to increase of strength and decrease of weight. The crank-shafts of marine engines are generally of wrought-iron, in one mass, the cranks being double, and forged with the shafts. Three bearings are deemed imperative, so as to equally distribute the strains. Now, this is correct in theory and practice, and the writer will be deemed committing a grave error no doubt, in mathematics, when he assumes that the forward frame and half-crank can be dispensed with, in order to reduce the weight and material. He is, of course, aware that the thrust and pull of the connecting-rod will be thrown on the centre crank and bearing, but, in order to counteract this, the length and diameter of the shaft at that part should be increased. He would also prefer, in this case, to extend the frame and connect the upper portion to the condenser; the cap being on the top instead of at the end, as now used. Screws might be employed to adjust the side brasses; the eccentrics could be within the cranks, or between them and the bearings.

Having alluded to the principal working details, I will now lay before you a description of the mode of condensation—past and present. It is well-known that the principle of condensation is to convert the steam into its original state. The contact of the cool fluid, in the shape of water, accomplishes this in the ordinary condenser, and cooling surfaces in the surface condenser.

In the days of the introduction of side lever engines, the arrangement of the condenser and air-pump was faulty; in some cases the foot-valves were almost inaccessible. Not many years ago, being on board a steam-ship fitted with old side lever engines, which were then undergoing repair, I noticed a rope and block tackle over near the condenser. On inquiring of the engineer how he progressed, the answer was, "I am just going to sling one of the men with this tackle, by the heels, to inspect the foot-valves; and that," said he, "is no foolish job." On further examining the engines, I found that an upside-down attitude was required, and indeed the only one allowed for the inspection of the valves in question. Happily now, however, such an inconvenient arrangement is of rare occurrence. We also find the side lever engine is being superseded by that of the oscillating type.

The arrangement of the ordinary condenser and air-pump for oscillating paddle-engines is generally as follows: the condenser is situated between and below the trunnions of the two cylinders; the air-pumps are at an angle, with trunks and connecting rods of the ordinary kind; the foot-valves are at the bottom of the barrel of the pump, the piston has valves in it; and the discharge-valve, when not at the top of the pump-barrel, is at its side. Now, the principal defects in this arrangement are in the position of the valves and condenser. When the foot-valves are directly underneath the pump's piston, it is obvious that an almost entire disconnection must be made to inspect them. Also, in the case of the piston-valves requiring inspection, the pump-cover must be removed, and to attain this the gland packing has to be slackened, and the connecting rod disengaged. Now, to avoid these evils, doors might be introduced, but with these disadvantages—increased height or length of the air-pump passages, and a body of water always above and below the piston, which undoubtedly is what any right-thinking engineer would disapprove of, it being clearly understood that an air-pump will produce a better vacuum when the piston thoroughly discharges the contents between the foot and delivery-valves at each stroke.

Having thus pointed out the existing evils of the

ordinary arrangement, it will not be deemed out of place to introduce a remedy. The condenser at the side of, or below, the pump is in one of the worst positions that can be conceived; the idea of allowing the condensed steam to fall, only to be raised again, seems, on consideration, to be foreign to the ideas of our talented engineers. It is well known that, in ordinary arrangements, the condenser is always in the position alluded to; steam even of a low pressure is larger in volume, but not as dense and heavy as water; it is also more elastic, hence it will more readily ascend. This, then, being clearly understood, it is not unwise or impracticable to assume, that if the condenser were on the top of the air-pump, instead of at its side or bottom, a better vacuum would be maintained. I beg to offer a description of an arrangement of condenser and position of the valves, both for correct action and accessibility. It will be understood that the condenser in this case is over the air-pump; the suction-valves are inverted, consequently the weight of the water assists the action of the piston in causing a vacuum. The exhaust-steam from the cylinders rushes up the exhaust-pipe, and enters on the top of the condenser. The water in the air-pump is discharged through the delivery-valve, at the top of the pump, and from thence through the delivery-valve at the ship's side. A door is secured opposite the delivery-valve, and doors are provided on each side below the bottom of the condenser, for the double purpose of inspecting the suction-valves and the air-pump piston.

This arrangement of condenser and air-pump will occupy as little room as those of the ordinary kind, with the advantage of accessibility to all the working parts without disarrangement. It may be argued that the stuffing-box, being in a recess when used for guides, would be troublesome to keep tight or repack, but if oil be always kept in the recess, so as to entirely cover the gland, it would tend to lessen the liability of leakage; the nuts of the gland and bolts could be adjusted by a box-spanner, or the bolts prolonged to the top of the condenser. In cases where the depth of the ship would admit, the recess could be dispensed with; trunks are not proposed for this arrangement, as their diameters would be necessarily increased, owing to the length required to pass through the condenser, unless a recess were resorted to as now proposed.

The next portion of the subject now before us is the ordinary condenser for screw engines. The action of the air-pump in this case is usually horizontal, consequently the valves are at right angles to the pump. To describe each arrangement of condenser and air pump that have come under the writer's notice would occupy too much time, consequently a brief mention of two or three examples on this occasion will be deemed sufficient. For direct-acting and trunk engines, with the cylinders secured together or side by side, the condensers were between, and, in some instances, in front or at the sides of the air-pump. The foot and discharge valves were directly over each other, the former under the pump at each end, the condensed water or steam being drawn through the foot valves and forced through those above. In another instance the foot and delivery valves were extended the entire length of the air-pump and passages, the position of the valves over and under being as before, and the condenser being between the air-pumps. For return connecting rod engines, the condenser and air-pumps are subject to great disadvantages. In order to obtain a passably good arrangement, and, at the same time, occupy a moderate space in proportion to those last mentioned, the condenser, &c., have to be shaped to suit the purpose required. It must be perfectly understood that when the piston rods are beyond the crank shaft (as in the examples now in question) there is a certain amount of space required for the piston-rods and guides of the cross head, or guide block, whichever may be used. It is also clear that accessibility to all the valves without disarrangement should be attained. To illustrate these desiderata the following examples will be sufficient for

the present purpose:—In one instance the condenser is partially between the cylinders, and extending beyond the crank shaft; the air-pumps are at the side of the condenser; the suction-valves extend the length of the air-pump; and the discharge valves are between each pump, the pump and the valves being beyond the crank shaft.

The next example is as follows:—The condenser and its appendages are entirely beyond the crank-shaft. The air-pumps are at the extremity or sides and near the bottom of the condenser. The foot and discharge valves extend the entire length, and are arranged over and under the pumps in the usual form. The guides for the piston rods are between the upper portion of the condenser and that of the discharge chamber.

Having disposed of the principal arrangements of air-pump and condensers as formerly constructed, allusion will now be made to those of recent improvement and practice. As before stated, a better vacuum can be attained when the condenser is over the air-pump instead of at the side. For direct-acting engines there are two arrangements specially worthy of notice. 1st. The air-pumps are worked by the steam-pistons between the cranks as near the base lines of the engine as the periphery of the circles will admit, the condenser being one chamber, directly over the air pumps. The suction valves are inverted in the bottom of the condenser, so as to effectually drain the same. The discharge chamber extends the entire length on each side and back end of the condenser, the valves being nearly in the same line as those for the suction, but reverse in action. The next example is the same as the last in principle, although different in arrangement. The air-pumps are situated as in the last example, but the condensers are separate, one to each engine, over and on each side of the air-pump. The suction valves are inverted in the bottom of each condenser to obtain the advantage before alluded to, the discharge chamber and valves being central or between each condenser, and directly over and between the air-pumps. It may now be argued, that if the two examples last mentioned are perfect in action and arrangement, what is the cause of the diversity? The answer to this is, Diversity of idea. Engineers, as a rule, are averse to the act of copying from each other. No sentence grates more harshly on the ear of a scientific man than the words, "Where did you copy this," or is more repugnant to his dignity.

Having referred to the improvements in the arrangement of condensers, &c., for direct-acting engines, attention will now be given to those adopted for double piston-rod engines. It must be borne in mind that for this class of engine the prolongation of the piston rods beyond the crank-shaft greatly deteriorates the arrangement of the air-pumps and condensers, in relation to the space occupied by those for single piston rod engines. In the examples now given, the air-pumps are worked by the steam piston, and as near the base line as possible. The condensers are separately arranged outside the guides of the piston rods of each engine; the suction-valves are inverted above the top of the air-pump, as in the last examples; the discharge chamber is between the air-pumps and the valves, on the same level as those for the suction. It will thus be understood that both suction and delivery are at the side, over and extending the length of each air-pump, instead of being directly over them, as in some cases.

The next example worthy of notice is arranged as follows:—The condensers and their appendages are beyond or outside the guides of each engine, the air-pumps deriving their motion as in the previous examples, and are as near the base line as possible, so situated as to clear the guides. Partially over and beyond the side of each air-pump are the discharge valves, above which is the discharge chamber; over this, and at the side of the same, is the condenser with the suction valves inverted.

I will now allude to the system of condensation known as surface condensation. Mr. Hall, in days of yore, intro-

duced the tubular arrangement with great advantage. Engineers at that time were slow in appreciating the then presumed gain, and it is only lately that we have seen the surface condenser universally adopted by the powers that be. To condense steam properly is undoubtedly to reduce it to its natural or original state. Now, in the ordinary condenser we bring water into actual contact with the steam to condense it. Surface condensers are to be recommended, particularly for one reason, viz., the production of distilled water for the feed of the boilers. The arrangement of the tubes in surface condensers entails practical difficulties as to the position most suitable, whether they be inserted transversely, perpendicularly, or longitudinally, of the hull of the ship, renewal of the tubes being often required (sometimes while at sea) from corrosion.

The means adopted to render the connection of the tubes in the plate air-tight are numerous. The usual mode now is—india-rubber rings recessed in the plates encircling each tube—compression being obtained by a nut for perpendicular tubes, and by the vacuum in the condenser for those of horizontal positions;—this is simple and efficacious, and at the same time economical. It must here be remarked, however, that compression of the india-rubber by vacuum can only be attained when the steam is condensed by the external surface of the tubes or within the plates. The circulation of the water is either through or surrounding the tubes, and is produced by pumps with plunger-piston or centrifugal action. The position of the piston-pumps is horizontal, motion being derived either from the steam-piston or piston-rod. The centrifugal-pump requires a separate engine, or spur-gearing, &c., from the crank shaft to give the required velocity.

The values of the two arrangements now used for the condensation of the steam are about equal. In the case of the water surrounding the tubes, the steam passes through the same, and in the case of the steam surrounding the tubes the position of the water is reversed.

It is obvious that where internal condensation is effected a greater number of tubes are required, in relation to those of the external system—the inner surface of the tube being less than that of the outer. The advantage gained by the steam entering the tubes may be said to be—access for cleaning without disarrangement. Injection, or ordinary condensers, are more generally used than those of the surface kind, on account of economy in the outlay of capital at the commencement.

The injection-valves for ordinary condensers are generally of the solid or gridiron type, the latter to reduce the stroke to open and close. The pipe for the dispersion of the water is usually a tube, with apertures, of an elongated or circular form. An improvement has lately been made in these pipes, by contracting the area for one-half the length, thus equalizing the diffusion of the water throughout.

The next valve necessary for the condenser is the lifting valve, which is a single disc of gun metal, with a slight spiral spring at its back, or upper part. A screwed spindle is universally used to prevent the valve from rising, after the water and air in the condenser has been blown out previously to starting the engines. It might be deemed neglectful if I were not to make allusion to the bilge injection-valve or cock, whichever may be used. This valve, as well-known, is only required in cases of necessity, such as leakages, or disarrangement of the bilge or donkey pumps. I would beg to suggest that the bilge water should not be allowed to enter the condenser, on account of the generally impure state of the bilges. A valve and box might be arranged at the end of the air-pump for this purpose.

The portions of the marine engine next for exemplification are the feed and bilge pumps. The position of these is so arranged that a free access can be obtained to the valves and surrounding parts without disarrangement. Some makers prefer to work the feed and bilge pumps in a line with each other, with one rod and plunger direct

from the steam-piston. Other firms secure the pumps side by side to the discharge water-pipe of the condenser, each plunger being connected to the piston-rod crosshead; this latter improvement is more general than the former. In the case of hollow plunger or trunk air-pumps, those for the feed and bilge are on each side of the air-pump, and secured by nuts or keys. Before terminating this portion of the subject, it will be well to add that the valves for the air, feed, and bilge pumps are now universally discs of India-rubber, instead of the gun-metal spindle-valves.

It will have been observed that no allusion has yet been made to the arrangement of combined high and low pressure engines. For the purpose of comparison I will allude only to those arrangements in common use. The position of the low-pressure cylinders is side by side, as for those of the ordinary kind; in some cases annular cylinders are used, viz., the high-pressure cylinder within that for the low pressure. Another arrangement is the high-pressure cylinder on the top of that for the low pressure. A third arrangement has the smaller cylinder at the back end of the larger. A fourth example consists of two high-pressure cylinders in front of one for low pressure, the former acting as guides for the piston-rod. The means adopted for imparting the motion of the piston to the cranks are of the ordinary arrangements already described, with the exception of the necessary extra piston-rods and stuffing-boxes.

Having alluded to the different engines, and their details past and present, adapted for the single screw, I will now call attention to a notice of arrangement of engines as at present used for the twin or double-screw system. It must here be mentioned that the class of engines now under notice have precisely the same duty to perform as those before described, consequently, if I pass over the major portion of the detail it is to avoid repetition.

The arrangement of the engines is usually separate for each screw. The type of engine generally adopted at present is direct-acting with surface or injection condensers. Single piston-rod engines seem to be more in favour than those of the double piston-rod return action type, I presume on account of the simplicity of the former. The position of the arrangement in plan is side by side—port and starboard—instead of directly opposite each other; this is owing to the space required for the arrangement adopted, and the small beam of the vessel; but in some cases engines are arranged opposite each other, with a great reduction of space compared to that of the side system. When the crank shaftings are connected the steering principle is destroyed, and the twin screw system, so far as regards propulsion, is very little better than the single system.

There is not the least doubt that as a mode of steerage the twin system is correct, and for shallow draughts it is advantageous. To suppose the plan to be universally correct for large vessels requires, however, more practical evidence than I at present possess; but of this I am confident, that for small or large vessels, whether for commercial or war purposes, the twin screws, when driven separately, are invaluable for steering. The advantages for war ships are principally the facility for manœuvring when under an engagement. Let it be presumed that the enemy has aimed at a twin-screw steamer, by a contrary action of the screws her position can be shifted instantaneously, and the intended evil postponed, if not averted.

I have come to the end of my brief description of the marine engine, and will now allude to the weight of material, cost of marine engines, and the relation of nominal to actual horse-power, together with the consumption of fuel. The variation in the weight of marine engines is due to the design and arrangement as much as the material used. Double trunks may be said to be a fair example as to the average weight of marine screw engines. Return connecting rod engines are perhaps the heavier, in comparison to those of the single type, in relation to rods

and guides. High and low pressure engines combined are the heaviest of any examples yet given. The materials comprising the different portions of the engines of the present day are of six kinds—first, cast-iron, of which is formed the cylinders, pistons, valves, casings, main frames, guides, condensers, &c.; secondly, wrought-iron, comprising cranks and shaft, piston and valve rods, links, levers, weigh-shafts, bolts, nuts, &c.; thirdly, steel for springs, small pins, &c.; fourthly, gun metal for bearings, guide blocks, bushes, glands, nuts, &c.; fifthly, copper, for pipes of all kinds required for steam and water; sixthly, india-rubber, for valves, packing, &c. For the present occasion, in reference to weight, I have selected twelve examples of marine screw engines, each varying in power and design. The examples of arrangement being in pairs, the result has been that 4·834 cwt. per nominal horse power may be taken as the average weight of material, exclusive of boilers, fittings, screw-propeller, and alley-shafting. It may here be observed that each maker of marine engines in the present day differs in design and arrangement, consequently the weight of trunk engines by different makers would be unequal. The same may be said for single piston rod engines, as well as for double piston rod return connecting rod engines.

I now come to that portion of this subject which is the crowning question of all, and too often the cause of much controversy in political and commercial circles, viz., what is the cost? My opinion is, that it is perhaps the most difficult query to answer that could be put, and the only reason for its introduction is to preserve myself from presumed neglect in not noticing this important matter. To ascertain correctly which is the cheapest class of engine at present in use, is a problem much too difficult for me to solve; but I will, however, tender such information as I deem reliable.

The price of a marine engine depends entirely on the class of workmanship. Should a roughly-finished engine and boiler be required, with more painted than polished surfaces, the cost will be reduced in comparison to that of the more highly-finished. The fittings also greatly regulate the outlay. Some companies pride themselves on this portion of display, others, again, look on it as an unnecessary expense; so, to draw a correct line of comparison would involve the amalgamation of the many ideas in order to give a fair evidence. I feel confident, however, that marine engines, with boilers and fittings complete, can be produced of certain classes, for £70 per horse-power nominal, and the same can be reduced to £50 per horse-power, each price of course being under certain conditions as to terms and workmanship.

Allusion must now be made to the power, &c., of marine engines. Nominal power is a term used particularly for commercial purposes. Each maker has his private rule, hence the difference in dimensions in engines of the same class and power. Actual horse-power is defined by the indicator diagram, speed of piston, &c.; the ratio between the nominal and actual power is in some cases low, in others high. The writer has known instances where, the nominal power being 1·0, the actual was 6·0; and in others, nominal 1·0, actual 2·123; the average ratio at present is nominal 1·0, actual 4·0 to 5·0. With reference to the consumption of fuel, there is a great difference in the evidence. Superheating and surface condensation are slowly making progress, and at the same time reducing the consumption of fuel in ratio to the amount of water evaporated or steam used. The average actual horse-power expended per cubic foot of water evaporated is, water being 1·0, actual horse-power 2·635 to 4·0, and doubtless in some cases more. The ratio of fuel consumed in lbs. per hour, to the actual horse-power per hour expended may be taken as follows:—Engines of ordinary construction, power, 1·0; fuel, 5 to 6. For expansive working-engines, with superheating and surface condensation, thus:—Power, 1·0; fuel, 2·60.

I am deeply indebted to several eminent firms for

TWIN SCREW PROPULSION.—TABULAR STATEMENT OF SHIPS, MARINE ENGINES, &C., CONSTRUCTED BY MESSRS. DUDGEON, BLACKWALL, SINCE 1851 TO THE PRESENT DATE, SUPPLIED BY THE FIRM.

Total number constructed by this firm, from 1851 to 1864 inclusive—Screw engines, 87; Paddle engines, 39.

their courtesy and the practical information received and personally given. Messrs. John Penn and Son, of Greenwich, have kindly given me a tabular statement of much value to the profession and the Society. I am advised by this firm that a more extensive list of their trunk engines may be found in the *Artisan* journal for March, 1859, and November, 1861. The list now presented commences from the latter date; also that with their class of engines the consumption of fuel is about 4lbs. per actual horse-power per hour for those of ordinary construction, and about 2·5 lbs. per actual horse-power per hour for expansive engines, with superheated steam and surface condensation. This firm has displayed a warm interest in the present paper, by kindly lending the photographs and splendid working models, which I have the pleasure of laying before you.

Messrs. Maudslay, Sons, and Field have kindly lent photographs of their late improvements in marine engines. From personal interviews, I am enabled to present the Society with valuable information, particularly as follows:—The amount of fuel consumed, per horse-power actual, for ordinary engines by this firm is 5lbs., in some cases less and in others more. For three cylinder expansive engines, with surface condensation and superheating, the consumption is reduced to 2·25 to 2·5 lbs. per horse-power actual. These engines cut off at one-seventh of the stroke producing an almost correct indicator diagram. In one example shown me, the nominal horse-power was 150; with a pressure of steam 25 per square inch, the indicator diagram produced a result of 875 actual horse-power, being in the ratio of 1 to 5·833, which may be said to be an exceptional result for screw engines. This firm has constructed, since 1851 to the present time, the following number of engines and boilers:—Of screw engines, 183; of paddle-wheels, 30. The highest nominal power of one pair of engines yet constructed by this firm is 1,850, and the lowest 10.

The Messrs. Rennie have kindly lent me models and photographs of the different classes of engines they are in the habit of constructing. I am informed by this firm that the consumption of fuel for ordinary engines is—Actual horse-power 1, fuel 5. In the case of surface heating, surface-condensation, and expansion—

Actual horse-power, 1, fuel consumed 2·5; showing a reduction of 50 per cent. on that of the ordinary kind, which is about equal to the other firms.

Valuable statistics have been supplied to me by Messrs. R. Napier and Son, of Glasgow, giving particulars of the ships, engines, &c., constructed by them from 1851 to the present time. From these I have made a selection for publication. This firm has also kindly presented me with splendid photographs of their engines, &c., which are hung for inspection.

With reference to twin-screw propulsion, I am deeply indebted to the firm of Messrs. Dudgeon, of Blackwall, they having kindly furnished for this occasion practical statistics of the proportions of vessels and engines constructed by them since the year 1851 to the present time.

In conclusion, I must apologise for the length of my present paper; but I beg to observe, that had I extended my remarks to twice or thrice the present length, I should even then have failed in doing justice to this subject, which is undoubtedly one of national importance. To the credit of those concerned it can be truthfully said, that, in comparison with other nations, the productions of our marine engineers maintain that high standard for excellency of design and workmanship which has ever characterised the natives of Old England.

DISCUSSION.

Mr. J. CLARKE said allusion had been made to surface condensers, which, he presumed, would render unnecessary the use of salt water in the boiler, inasmuch as the boilers could be charged with fresh water before leaving the port, and this was used over and over again. He was recently in the workshop of a member of the Society, who was largely engaged in the manufacture of salinometers, having then a large order to execute for the Government, but in the event of the universal adoption of surface condensers, he presumed that instrument would be superseded.

Captain JASPER SELWYN, R.N., said, as a naval officer interested in the progress of mechanical invention, he thanked Mr. Burgh for the information he had afforded

in his interesting paper. He would remark, in the first place, that only very slight mention had been made of boilers; but a man who took the interest, as Mr. Burgh evidently did, in mechanical questions, would never ignore the source of the power, or deem it unworthy of a place in his paper; for it was clear, so long as we went on with ineffective arrangements to produce the power itself, it mattered little how much economy was introduced into the arrangements for utilising the power. The steam boilers of the present day he considered to be a reproach upon the marine engineers of this country. They were very far from producing at any time anything like the results in practice which they produced when sent on trial trips. That was partly caused by the insufficient means of securing the circulation of the water in the boiler, and partly by the bad arrangement of the fuel for firing, by the choking of the tubes with smoke, and by the galvanic action which was speedily set up, and resulted in the deposit of large quantities of material all over the heating surfaces. In many ways the boilers required, but had not yet received, the same amount of attention that had been given to the engines. He thought improved means for securing the circulation of the hot water, and of preventing escape, of utilising fuel, and obtaining complete combustion, were of more importance than any improvement in the engines. He had heard of the introduction of steel with great pleasure, knowing how advantageous it would be in many respects; but if those who employed steel did not consider the electrical action which would result when that metal was brought into contact with copper, a deposit would be produced in the boiler which would go far to neutralise the other advantages. He was very pleased to hear incidentally introduced into the paper a subject in which he had for some years taken an interest, viz., that of twin screws. He was, however, at a loss to conceive on what ground it was said that the twin screw principle could only succeed in vessels of a certain size, and was not applicable to larger ships. No later than the previous day the newspapers gave an account of the trial of a vessel of 970 tons, fitted with twin screws, and the results, he had been informed by persons who were present, were correctly reported. Now, that vessel represented what would formerly have been called a large ship, and the question to be decided was—to what tonnage were the good effects of twin screws to be limited? In the first instance it was said that the principle was a good one for boats; and last year Mr. Rennie stated it had been tried with excellent effects in small river steamers, but he doubted the success of its application to anything beyond that. Subsequently to that, however, blockade runners, fitted with twin screws, made their appearance, and were completely successful, and since then the experiment had been tried on a still larger scale by ship-builders on the Thames. He deprecated such a decision being arrived at on this point as would prevent us from building vessels for our navy of such steering power as Mr. Burgh had recognised in the twin screws; besides this advantage, he (Capt. Selwyn) maintained there was also an increase of speed. They had a certain draught of water in a screw ship to which they were limited; they might put into the ship engine power as much as they pleased, but they could only utilise the area of water which came against the propeller. If they could increase that area they got more duty done by the engines without "churning" the water, and that was the whole theory of the success of twin screws in giving speed. That principle was perfectly applicable to a ship of war; and the vessel to which he had previously referred had another valuable quality: she gave, with a draught of nine feet six inches, a speed of 16½ knots with both screws working, and of 12 knots with one screw only working. This showed that even in that vessel the power of propulsion was not utilised to its full extent; the increased velocity did not correspond to the increased horse-power used. With regard to the

observations in the paper as to the reluctance of men to copy, he confessed he thought that class of intellect was more rare which knew how to judge properly what to copy, than that which invented for itself a new mode not always better than that which preceded it. The great masters in painting had numberless followers, who called themselves the scholars of those men; and it was no less a credit to these to have chosen well their master than to have produced something original. With regard to the comparison of fuel consumption, it must be recollected, when they got indicated h.p. in proportion to nominal h.p., as 4 or 5 to 1, and the coal burnt was now 2½ lbs., instead of 8 or 9 lbs. per h.p., there was not so very great an advance as might be inferred from the way in which the case had been put. Much more might be done in the way of economising fuel, by due consideration of the best way of placing the heating power advantageously in the boiler. It was clear, so long as they did not provide for the free descent of the hot water when it had given off its steam, and had become to a certain extent cool—the free descent from the top to the bottom to be re-heated, so long they lost the good effect of the boiler. The injurious effects of scale in boilers had been obviated to a certain extent by the employment of scale catchers or surface apparatus for laying hold of the scale as it floated up, but he thought the better way was to consider any system which formed less scale in the boiler, and with that view fresh water when once in the ship might be maintained in the boiler without trouble. They could produce sufficient fresh water for the purpose by the utilisation of a small quantity of fuel so as to supply whatever waste of water took place from condensation. With regard to the general arrangement of engines in ships, he quite entered into the graphic illustration in the paper of a man hung by his heels to inspect the foot valves. He thought engines were made too much like watches. Engineers prided themselves on the small space within which they could place their engines, and by that means subjected the persons who worked them to a great deal of unnecessary inconvenience.

Mr. ROCHUSON, as one practically connected with the manufacture of machinery, would express his dissent from the statement of the last speaker—that the contact of steel and copper in a boiler would generate a stronger galvanic current than that of iron and copper.—[Captain SELWYN said he had made no such statement.]—There was no doubt that steel was a very important element in all engines, and he regretted that subject had not been more dilated on in the paper; at the same time, it was well to give a caution as to the indiscriminate adoption of steel for boilers. Steel would bear a higher tension than the best Yorkshire iron, but certain qualities of steel were unfit for boilers from their liability to injury from blistering. The most suitable form of steel for boilers was cast-steel, which could be made of a strength equal to a pressure of 60 tons to the square inch. One great object sought in engines was the avoidance of heated bearings; and the more they reduced the surface of the bearings, and the more they employed metal capable of a highly polished surface, the less were they liable to this evil. The use of cast-steel for shafting was, therefore, a great advantage. It had been found by experience that a cast-steel shaft of nine inches diameter was equal in strength to one of 11 inches in wrought iron. In that proportion, therefore, they saved material in the weakest part of the ship, and they had a stronger construction with less strain upon the engine. They might go from that to cast-steel propellers. There was scarcely a greater annoyance on a voyage than the breaking of a propeller. In one short voyage in one of his vessels, no fewer than five cast-iron propellers were broken. They were not, perhaps, at that time quite up to making good cast-steel propellers, but he believed they were so now. The first cost would be greater, but that was more than compensated by the safety and durability which were insured.

Captain SYMONDS, R.N., reverting to the subject of the twin screw, said that Mr. Burgh, while giving credit to that system for a certain number of advantages, had omitted two or three of the most important. During the last five or six years he had seen something of the practice of the larger class of twin screw vessels, and it struck him that one of the principal advantages of the twin system was that in the event of one engine or one screw becoming injured, they had the use of the other engine and screw, by which two-thirds of the power could be obtained in case of emergency. This was exemplified in the trial of the vessel alluded to by Captain Selwyn, when one of the engines being stopped, owing to heated bearings, she was propelled at twelve knots with the other engine; her full speed being rather over sixteen knots. That was a very important thing, especially in a merchant ship, as had been proved in a voyage to America. A twin screwship had been able to proceed with fair speed and slight consumption of fuel with one engine, while the other engine was being repaired; so that when she arrived out her engines and boilers were in a good condition to run the blockade without any occasion for delay. If that ship had had only one pair of engines applied to a single screw it would not have been so capable of performing this service. With respect to the limit of size of ship to which the twin system was applicable, his gallant friend Capt. Selwyn's remarks on the subject rendered it unnecessary for him to go over the same ground again, but he would add that it was of the utmost importance to have the twin system adopted in heavy ships in order to divide the power between two engines, which ordinary engineers would then find no difficulty in manufacturing; besides, it was found difficult on board ship to lift out the heavy parts of very large engines for repair. He submitted also that the moving parts of these large engines in heavy ships were not so convenient as lighter machinery would be. Another great point was the difference in the amount of friction between the heavy single screw engines and the lighter engines on the twin system. In addition to these advantages, there was that which was derived from the position of the twin screws, away from the centre of the ship, which not only gave them a great advantage in propulsion, but also placed them away from the extreme end of the dead wood, where, from the longer leverage, greater vibration would necessarily be produced. In fact, the single screw produced an amount of vibration which was avoided in the twin screw system. Experience had shown that the twin principle had been applied with the best results to vessels of various sizes up to 500 tons, and within his own knowledge one of these vessels had been doing regular work in towing for the last six years. With a draught of only 3 feet 3 inches, and engines of 30 horsepower, she had been continually towing four Dutch barges, with loads of 50 tons each, at six knots an hour, which was a result, he believed, seldom obtained by paddle-wheel tugs of the same power and draught of water. The engines were in as good a state as when they were first built, and they had never been known to hang on the centre, which was one of the objections to the single screw engine. He had found the twin system effective for two main reasons. In the first place, the arrangement of the inverted cylinder engines on the A frame occupied no more room in the ship than a pair of ordinary screw engines, with this further advantage, that it did away with even the slight vibration which was found in vessels of the same character with the engines laid horizontal. He submitted these were points of advantage which ought not to be lost sight of.

Mr. G. F. WILSON, F.R.S., remarked that on the first introduction of surface condensers a difficulty was experienced, which he should be glad to hear had been obviated. It was found that the oil used for lubricating certain parts of the engine was carried with the water into the boilers, and there, as was well known to chemists, when oil and water were brought together at a high temperature, the oil became separated into its acids and base, the acids being

free to act upon the material of the boiler, and upon any impurities contained in the water. This was found to be an important objection to the surface condensers. He should be glad to know whether that objection had been removed. In addition to this the steam was not generated so quickly. It was proposed at one time to use oil not composed of acids and a base, such as mineral oil, which, it had been thought, would not be decomposed by the action of the water, but he had no means of knowing whether this succeeded or not.

Mr. JOHN GRANTHAM remarked that the double screw system had entered somewhat largely into this discussion. It was a subject of great interest at the present time, and the naval officers who had addressed them had spoken encouragingly of its advantages. There were to this question, as to all others, two sides. The system seemed to be a very captivating one, but he thought its advantages had been somewhat overrated, and they must be cautious not to take up too readily the few examples, which had been presented under perhaps the most favourable circumstances that could be obtained, and to suppose that the system therefore had all the merits which those particular vessels were shown to possess. The builders of those ships understood their business well, and built fast vessels to which they applied the twin screws, and we did not always weigh carefully how the great success had been produced, and whether the same results, or nearly the same, might not have been produced by the single screw. It was, therefore, not unnatural that naval men, who had to do principally with ultimate results, should be very much taken by these experimental vessels, but he feared, when they had had longer experience, some of those advantages would smooth down. As yet there was no proof that two screws would propel a vessel better than one, all other things being equal. He admitted that, if they had a vessel of light draught, and put very high power into it, probably two screws would show a better result than one, from the fact that they gave a larger surface under more favourable circumstances for propelling the vessel and utilising the power given to her. But he asked the engineers and naval men present to consider all the circumstances of the case. If they wished to have a screw vessel of light draught and great power, the double screw might be best; but if they were not limited as to draught of water and did not require excessive power, the single screw would be best. One disadvantage of the twin screw system was that it made the interior of the ship more difficult to deal with than when there was only one shaft and one set of machinery. If they could apply all the power favourably to one screw, he thought it desirable to do so. It would not, however, do to dogmatise on this subject; and, whilst he would not advise them to neglect this question altogether, he would caution them against thinking the system possessed all the advantages which had been urged in its favour as having been exhibited in the very fast and well-built vessels which had been recently brought before the public.

Mr. W. HAWES confessed his surprise at the observation of one of the naval officers who had spoken, that he considered the boilers on board a great many of our ships were a disgrace to the present state of science. When they found it to be the fact that the quantity of fuel consumed had decreased from an average of 6 lbs. or 6½ lbs. to 2½ lbs. per indicated h.p., he thought it showed a great amount of progress. That result might be obtained, not simply by having the best form of boiler, and the best mode of applying the fuel, but likewise by the perfection of the machinery which was driven. The measure was the fuel required, not to evaporate a given quantity of water, but to drive an engine of a certain power. That engine would be driven with the less steam, the more perfect was the machinery; therefore, the consumption of fuel was not only a test of the efficiency of the boiler, but also of the machinery which was driven by it. Undoubtedly, he agreed that

the economical utilisation of fuel was one of the most important elements of progress in marine engines. There were two difficulties staring the engineer in the face—first, how to put the largest amount of available power on board a vessel of a given size; and, secondly, how to stow sufficient coal to make that power effective for a long voyage. In all long voyages, the period during which a vessel could run under steam was so limited that it was a matter of the greatest importance to make arrangements by which a supply of fresh fuel could be ensured at frequent stations. For his part, he believed the progress in the construction of boilers had kept pace with the improvements that had been introduced into steam machinery, and that our present boilers, so far from being a reproach to our engineers, were evidence that they had been as successfully occupied in this branch of manufacture as they had in the production of the most perfect machinery the world had ever yet seen. With respect to the twin screw system he was inclined to think if that plan had hitherto been the ordinary one for propelling vessels, and the single screw were introduced for the first time, we should be struck with the simplicity of the machinery required in the latter instance to produce the same results. In the statement of the work done by the twin screw ships, there was an omission of the speed obtained by each vessel; but in the table furnished by Messrs. Penn this information was given. The very feature by which alone we could judge of the real value of the twin system was omitted. The adoption of twin screws, it was to be remarked, involved a double risk of fouling, and if there was one difficulty more than another with regard to screw ships, it was the accidents which happened to the propellers from fouling with substances floating on the water, and certainly two small propellers were more likely to be injured in that way than one large one. Moreover, the hold of a vessel was better adapted for one pair of engines with one shaft and one screw, than for having all those parts duplicated, and consequently weaker and more liable to derangement. Although there might be advantages in this system for shallow waters and light draught, he believed where the screw was well immersed the single propeller was more effective. They could not but feel much indebted to Mr. Burgh for bringing this subject before them; whether connected with war or peace, with the navy or the merchant marine of the country, there was scarcely a question of equal importance to the nation. It was essential that we should have the best ships, the best boilers, and the best engines, to enable us to perform the longest voyages in the shortest time with the least amount of risk to the lives and cargoes conveyed.

Captain SYMONDS begged to state that there had been no instance recorded of the fouling of twin screws, and he believed they were far less liable to foul than the single screw.

The CHAIRMAN said, looking to the title of Mr. Burgh's paper, they must all agree that a very fair description had been given of what steam engines were in the year 1851 and of the improvements that had taken place since that time. To go into all the details of this subject would far exceed the limits of a paper; but, nevertheless, it had led to an interesting discussion, and in itself conveyed a great number of valuable details. The question of twin screws was perhaps the most important one that had been touched upon, and he agreed with Mr. Grantham that in an ordinary passenger and cargo, or mail ship, with considerable draught of water, the single screw would probably give as efficient results in speed and economy of power as the double screw; but where a great amount of power was required to be applied to a vessel of limited draught, as was the case with blockade runners, the double screw might do more than could have been done with a single one; and he would further express an opinion that in the manœuvring of ships of war in action, the double screw system no doubt conferred many advantages. He

might remark that Captain Selwyn appeared to be a little mistaken with regard to the consumption of fuel. He understood Mr. Burgh to state that the consumption of coal had been reduced from 7 lbs. or 8 lbs. per indicated horse-power to as low as 2½ lbs. Perhaps the first was rather too large a figure as applicable to ten years ago; but his own impression was that the engines of good makers had worked with a consumption of not more than 1½ lbs. to 1¾ lbs. per indicated horse-power, which, compared with ten years ago, was a very great saving, and he thought our marine engineers ought to be gratified rather than otherwise that they had thus far succeeded in economising fuel. He now begged to propose a vote of thanks to Mr. Burgh for his interesting paper.

The vote of thanks having been passed,

Mr. BURGH acknowledged the compliment, and in reply upon the discussion, said he thought the advantages of the twin screw system were principally connected with the facilities for steering. With regard to the size of ship to which that system should be limited it was impossible to lay down any rule, because it must be borne in mind that it was more than probable that very heavy ordnance would be brought into use on ship board, so that very large vessels would become necessary, and then increased steerage power would be most valuable. The problem to be solved was whether the twin screw system admitted of universal application regardless of size and other conditions. Of that, he repeated, he required more evidence than had as yet been presented to him. With regard to the question that had been asked as to whether the accumulation of scale in the boiler had been prevented, he would say, if they used proper water in the boiler when they commenced working it, and if they took a sufficient supply of it to obviate the necessity of using dirty salt water, employing at the same time surface condensers, the scale in the boilers would be very greatly reduced. In reply to Mr. Wilson he would say, he thought the water was generally taken from the condenser, where but very little oil was presumed to be. Sometimes, it was true, in lubricating the internal portion of the cylinders, a certain portion of oil would get into the condensers, but not to an extent likely to prove injurious to the boiler.

At the conclusion of his remarks, Mr. Burgh explained the action of the equilibrium slide valve, and described the models and drawings lent by the several firms named in the paper, to whom the thanks of the Society are due.

Proceedings of Institutions.

BIRMINGHAM AND MIDLAND INSTITUTE.—The report of the Council, presented at the annual meeting, January 9th, says that although the Council are still unable to report the completion of the new buildings for the purposes of the free library and gallery of art, considerable progress has been made in their erection. They have received from Mr. Samuel Messenger a liberal offer of a pair of entrance-gates, after a design to be furnished by the Council. It is with sincere regret that the Council have to record the death, in March last, of Mr. William Oliver, who had acted as secretary of the Institute almost ever since its establishment, and who had so zealously fulfilled the duties of that office, as to earn the respect and esteem of all with whom he was brought into contact. The Council appointed as his successor, Mr. Edwin Smith, who had previously held the office of assistant secretary. Several valuable donations have been received during the past year, especially a spectroscope given by Mr. Pendleton, a former student in the industrial department. During the year thirty-two lectures have been delivered. Among these may be mentioned "Iceland and its Geysers," by the Rev. C. P. Wilbraham, Rural Dean of Newcastle; "History of Writing," by Mr. H. Noel Humphreys; "The Chemistry of Explosive Compounds," by Alfred Hill, Esq., M.D.; "The Grave and Gay in

Art, as exemplified in the Works of W. Blake, the Visionary, and George Cruikshank, the Humourist," by Sebastian Evans, Esq., M.A.; "The History of Gothic Window Tracery in England," by the Rev. T. N. Hutchinson, M.A., F.C.S.; "The Aymara Indians of Peru and Bolivia," by David Forbes, Esq., F.R.S.; "The Three Centenaries of Shakspeare," by Mr. Samuel Timmins; "Thackeray and his Works," by George Dawson, Esq.; "English Art in the days of Shakspeare," by Professor Chamberlain; "The Classification, Geographical Distribution, and Geological Relations of the Class Mammalia," four lectures by Professor Owen; "The Life, Character, and Oratory of Burke," and "The Life and Times of Washington," by C. J. Plumptre, Esq., Lecturer on Exon at Oxford; "English Literature. The Anglo-Saxon Period," by the Rev. Alexander J. D. Orsey, B.D. The Council have been anxious to render this part of the operations of the Institute as interesting and attractive as possible. The attendance shows a progressive increase. The bequest by the late Sir Francis Scott of his valuable collection of Limoges enamels was mentioned in the last report. The pecuniary legacy which accompanied the bequest has enabled the Council to provide a fitting case for them, and they have been placed in the museum. The Council record with great gratitude the generosity of Lady Scott, who took upon herself the entire burden of the legacy duty on the bequest, so that the enamels passed to the Institute as a free gift. The Council also express their obligation to Professor Chamberlain for his very elegant and appropriate design for the case. It is a subject of regret to the Council that the very limited space at their disposal for the museum prevents the taking of any active steps for making any considerable additions to the collection. It is, no doubt, to the want of novelty arising from this cause that it is to be attributed a falling off in the number of visitors during the year. They have numbered only 1,229, as against 1,617 in 1863. The specification library has, during the past year, been more consulted than in any previous one. It has been visited by 705 persons in 1864, as against 626 in 1863, and 578 in 1862. In all probability, before the preparation of the next annual report, this valuable collection of books will be transferred to the walls of the free library. In the industrial department, the classes have been carried on with increased vigour and success. The aggregate number of students attending the classes by virtue of quarterly payments, has been, during the past year, as follows:—Winter term, 410; spring term, 377; autumn term, 530. These numbers do not include the classes to which the admission is by payment of one penny at the doors. These last-mentioned classes (which are chiefly composed of artisans) have largely increased. During the autumn term of 1864 the average attendance at the elementary arithmetic class has been 182; at the penny lectures, 100; at the elementary singing class, 118; making a total weekly average of 350. If this be added to the number of quarterly students it gives a total of nearly 900 persons receiving weekly instruction in connection with this department. Very marked success has attended the instruction, as tested by the public examinations, both by the Department of Science and Art and by the Society of Arts, a larger number of Institute students having entered the lists than in any previous year, and, while on the one hand the general average of success has been far higher than on any previous occasion, the number of failures has been less. An inaugural address was delivered by the Right Hon. C. B. Adderley, M.P., the president, at the opening of the session. It was stated in the last report that the sum of £81 8s. 2d. was required to free the Institute from debt. This has been paid through the generosity of William Scholesfield, Esq., M.P., the president of the year, who kindly sent a cheque for that amount. The industrial department has been more nearly self-supporting than for several years past. The deficiency in that department amounts to £82 17s. 7d. In the general department there has been an excess of

income over expenditure of £147 18s. 8d. The reports of the teachers in the various classes are most favourable.

DUBLIN INTERNATIONAL EXHIBITION.

His Royal Highness the Prince of Wales has announced his intention of opening the Exhibition on the 9th May.

The different foreign advices already received by the Executive Committee show that much progress is making to obtain interesting exhibits. In Canada, on the recommendation of Lord Monck, the Legislature has voted £1,000 for forming a small collection of articles. It is to include ores of copper and other metals; specimens of gold, slates, soapstone, chrome, iron, and serpentine marbles; samples of grains, hops, flax, maple sugar, and honey; sets of woods prepared for study or cabinet collections most useful in the arts, cabinet manufactures, &c.; articles of woollen manufacture, yarn and cloth, prepared skins and saddlery, implements, models, sets of newspapers and periodicals. A committee has been also formed in Sherbrooke, for forwarding a collection from the eastern townships of the province, on which Professor Miles, Lord Aylmer, Dr. Gilbert, and about a dozen other influential gentlemen, are acting.

The list of products sent on from Mauritius has come to hand, and includes specimens of the finest samples of sugar, for which the colony is famous, vanilla, a fine collection of fibres, woods, starches and grains, cigars and tobacco, matting, &c.

From Sierra Leone there will be fine collections of native products from different parts of Western Africa and the far interior, specimens of woods, the different kinds of trade beads in use, native jewellery, and other interesting articles which have been collected and shown at an industrial exhibition held in the island in February.

DIFFUSION OF ART AMONG THE MILLION.

The following recently appeared in the *Daily Telegraph*:—

When Wardour-street curiosity-shops advertise "articles of *virtu*," and critics glibly chatter about art, it is doubtful whether they know the solemn truth contained in the Franco-Latin and Anglo-Greek words which they employ. The Greek called the perfection of any result of human activity—the complete fitness of the means and manner to the end—its *areté*, and the Latins imitated and adopted the idea in the word *virtus*; both expressions conveying the same meaning of "manhood," "maximum excellence," "absolute finish." Both words were intended to signify that true Art should be like to that Nature which it copies; as perfect in material, design, execution, and use as the workmanship of the Power whom these old races loved to call the "master workman." Providence "scamps" nothing, leaves nothing half-finished, nowhere shows a careless design, or a lost chance for service or beauty; the pearl of the poorest oyster-shell is as lustreously spread upon it as the silken light upon the lily-leaf. Infinite upwards and infinite downwards; passing beyond our telescopes and evading our strongest microscopes; eternal in range both ways, creation is always the same in perfection of design and admirable adaptation. There is a "common object" of the microscopist, for instance—the dust from the sea-bottom at Barbadoes. Examine it with the glass, and you are at once in a fairy ivory-turner's shop, gazing at millions of shells, every one as perfect for its inhabitant as the great conches that roll up upon the African beach. Trunk of elephant or lancet of mosquito, each is perfect in its way, each for its uses. Art, human art, has to imitate at a distance this Divine accuracy and adaptation, which give good work and true to everything they deal with. And human art can do it so far as it carries conscience, knowledge, and effort into its toil. We may take as the simplest possible example

of "art"—of "vertu"—of excellence resulting from the humblest material and means—the water-pots of clay common to the East. They must carry much, with a narrow mouth; the handles must be sunk in the outline, to avoid accident; the price must be low, the substance strong; these are the conditions; and merely by complying with them in the *best possible* way, there has resulted a graceful traditional shape, which artists delight to import into their canvases, and cannot improve upon. Beauty has been silently and surely born out of the union of an earnest mind and a true hand, though the offspring is only a pipkin or jar. "Nothing common or unclean" should thus be the maxim of Art, as it is of the deepest philosophy. Everything has its "best"—its *vertu*; and everything is worth making of the best, and in the best manner, that is worth making at all.

These are platitudes! Unquestionably; but they are platitudes which were neglected almost universally among us within the memory of middle-aged men. "Art," to so recent a date as 1851, was with the million, and with a good many who looked down upon the million from the sublime heights of the "upper ten thousand," quite a different thing from the ideal to which we have referred. "Art" was merely painting a picture, chipping a statue, modelling a teapot, carving a table, casting a figure, weaving a carpet; and it hardly struck the general public of these realms that the teapot, table, and carpet had each a *virtue* of form, construction, and colour, to miss which was to miss much or all. In Science we have always been pre-eminent; no nation has a roll more glorious than that from which a hasty enumeration can at once recall such names as Newton, Priestley, Cavendish, Smeaton, Arkwright, Watt, and Davy. But the real Art-education of the country did not begin till 1851. It is not that we wanted the faculty, as events have shown; the appreciation of good work was always to be found among us. But we wanted the impulse, and it came at last, in the year when the productions of the world were grouped in the great Glass Palace. England saw then that she had neglected, ignored, misunderstood Art—the Art, we mean especially, which, so well comprehended and studied by the French, stoops to the utensils of the cottage and to the uses of daily household life. The good Prince who bore so valuable a share in promoting the first Exhibition lent his influence to its corollary, the establishment of Art-education in England. Schools of Art were founded in the country under the direction of the Committee of Council on Education; a national museum, for examples of just and perfect workmanship, was created at South Kensington. We "began at the beginning," with an effort to reform our "pots and pans," by classes and prizes for drawing and design; and amid a good deal of inevitable merriment at the first crude proceedings of "the Brompton boilers," the community set steadily to its task, with the help of the Government, to learn how its wealth of material and solidity of workmanship could be made richer and better by beauty of colour, form, and fashion.

An important minute, just issued to Parliament by the Lords of her Majesty's Privy Council on Education, communicates the welcome fact that the idea now "runs alone." The laughers and jokers swore it was rickety from its birth; that the grants and encouragements which were administered to it were so much wasted pap; that it wouldn't and couldn't thrive; and that common things were good enough to eat and drink, and live with, especially for common people. But now Art-education has taken such a lease of life in the country that its foster-parents find they can let it shift for itself. A select committee of the House of Commons, after examining the subject, has recommended that the Schools of Art should now rely on their own resources; and the directing department of the Privy Council accepts and adopts the view. To prove how the study has flourished a very few figures will suffice. In 1851 the Parliamentary grant to Schools of Art was £6,850, for seventeen schools and 2,482 students, showing an average cost of £2 8s. per student;

while in 1863 the amount of subsidy was but £4,005, the schools being ninety and the students 16,180—in other words, each pupil "of the beautiful" stands us now only in the sum of four shillings and tenpence. The explanation is that manufacturers of every kind soon awoke to the existence of a native faculty for design, and that taste was an article no longer dispensed with or imported. Left to themselves, indeed, "my Lords" observe that they would not have withdrawn the grants just yet, and they object to curtail the indirect assistance which they extend to Art-education by the National Art School, or in prizes, studentships, and payments "by results." But the select committee is quite at its ease about the local schools, and they at least are henceforward to "run alone." The Council will still pay a grant for the night-classes of artisans, and also a capitation grant for children learning drawing; and we may remark that the grounds upon which they dissent from the proposal of the select committee to extend grants for adults seem sound. The child has to be brought to the study—the artisan must bring himself; and he will bring himself just in proportion as he sees it to his own benefit, and worth paying for from his own pocket. By the subsidy for children's drawing classes elementary instruction with pencil, pen, and crayon is put upon a distinct basis, and Parliament will be asked for a special vote for this useful purpose. The changes proposed do not affect the Kensington Museum, which will remain the central depository of Art examples, and which the Council very justly defends from extravagance, by showing that its treasures are natural possessions as well as educational machinery. We need not point out the satisfactory proofs of what Art-education, now firmly grounded, has done in the country; and what it will do would be difficult to exaggerate. It has removed true taste out of the connoisseur's cabinet into the poor man's reach, whence it will come back again through all grades of society, for be it remembered that the poor man is the working man.

Fine Arts.

THE COLLEGIATE SCHOOL OF STRASBOURG, in virtue of a bequest by M. Lamey, formerly Judge of the Civil Tribunal of that town, offers a prize of 3,000frs. for the best essay on the following theme:—"Should art be submitted to rules? On what do they rest? Are they absolute or relative, or partly one and partly the other? How is their authority to be reconciled with freedom of inspiration?" The prize is open to all the world, and the essays, which may be written in French, German, or Latin, are to be sent in by the 1st of January, 1867.

INDUSTRIAL ART EDUCATION IN PARIS.—The *Union Centrale des Beaux Arts appliqués à l'Industrie*, lately established in Paris, has just commenced its first course of lectures. The session was opened with an address by the President, and a short lecture on Archæology by M. Adrien de Longpérier, of the Institut. The following is the list of the remainder of the course:—Four lectures on Architecture and Artistic Industry, by M. Daviond; three on Glass Painting, by M. Ferdinand de Laeseyrie; one on the Sanitary Condition of Industrial Artists, by Doctor Caffé; three on the Grammar of the Arts of Design, by M. Charles Blanc; two on Sculpture, by M. Aimé Millet; one on Light and Shadow, by M. Fouché; and three on Ceramic Works and their Ornamentation, by M. Albert Jacquemart. This Society, already referred to in these columns, has made arrangements for a grand exhibition of objects of artistic industry in the Palais de l'Industrie this year, and offered the sum of 800 francs, in two prizes, for models or designs for the medals to be given on the occasion. The effect was far greater than any one could possibly have anticipated. No less than a hundred and forty-three designs and twenty-three wax models were sent in by seventy-nine candidates, and the society, sur-

prised by the excellence of the works, doubled its grant, and gave two prizes in each class.

PUBLIC MONUMENTS IN FRANCE.—The labour, talent, and expense bestowed on the public establishments and monuments of the country have been enormous. Extensive restorations and decorations have been executed in the two great edifices of Notre Dame and Saint Denis, as well as in more than twenty churches in various parts of the Empire. The ancient Cité de Carcassonne, the Roman theatre and amphitheatre of Arles, the Château de Falaise in Calvados, the Temple of Diana, and the Roman Amphitheatre of Nîmes, the Temple of Augustus and Livy at Vienne, the Abbey of Charlien, in the department of the Loire, the Oratory of the Templars at Metz, the Château of Pierrefonds, the Château of Blois, the ramparts of Avignon, and other monuments of historic interest have been repaired. Of the public establishments, directly or indirectly connected with art, the building where the archives of the Empire are kept has been largely extended, and the School of Archaeology annexed thereto has had a special building provided for it. The restoration of the Palace of the Institute has been completed; the arrangements of the new School of Fine Arts terminated; the old Château of St. Germain has been almost entirely restored, with the view of converting it into a grand museum of Gallo-Roman productions; the arrangements of the interior of the new Louvre have been pushed forward: a fine new gallery has been prepared for the works of the French School and thrown open to the public, a number of new rooms on both floors added to the gallery space in the new portion of the building, and several of the old rooms have been re-embellished and arranged at considerable cost; the corner building of the Tuileries by the river, known as the Pavillon de Flore, as well as a section of the grand picture gallery adjoining, have been completed as far as the masonry is concerned, and the whole of the remaining portion of the gallery has been levelled with the ground, and is now being rebuilt in the style of the adjoining work of Henry IV.; the reconstruction of the Bibliothèque Impériale has been energetically pursued, and the new reading-room, modelled somewhat after that of the British Museum, is covered in, and will soon be ready for occupation; the famous manufactory of Sèvres has been entirely rebuilt; and the new Opera House has been carried up from the basement to the first floor. This is a long list, perhaps the longest list of such works that was ever furnished by a single Government, but it is far from complete, although it includes all the principal works connected with art which have been supported by the budget of 1864.

STATUE IN HONOUR OF TENIERS.—The King of the Belgians has ordered a bronze statue in honour of David Teniers, the founder of the Royal Academy of Antwerp, to be erected in one of the places of that town. The Government contributes 18,000 francs towards the work, which has been entrusted to Mr. Ducaju, of Antioch.

PENSION TO MADemoiselle DE PUGET.—The Emperor Louis Napoleon has granted a pension of 500 francs per annum to Mlle. Fanny de Puget, the only surviving descendant of the famous sculptor of Marseilles.

THE ECOLES DES BEAUX ARTS not only in Paris, but throughout France, have been supplied with many models and casts from the antique, and copies of the works of the great painters. A class for the study of engraving on precious stones has been opened here, under the direction of M. Farochon. Pupils are admitted between the ages of fifteen and twenty-five. For foreigners the permission of the Minister of the Fine Arts is requisite.

Manufactures.

EXHIBITION OF ARTS AND MANUFACTURES FOR NORTH EASTERN LONDON.—On Thursday, the 9th inst., a meet-

ing of employers of labour and artisans interested in the manufactures of North Eastern London was held in the board-room of the Agricultural Hall Company, for the purpose of taking into consideration a proposal from the Provisional Committee of the North London Museum for a local exhibition of arts and manufactures during the ensuing autumn. The chair was taken by W. H. Bodkin, Esq., Assistant-Judge. The proposal was unanimously adopted, and also a resolution appointing a general committee of guarantors to make arrangements for carrying the same into effect. This movement is entirely unconnected with working men's industrial exhibitions, having solely for its object the promotion of the art-workmanship and manufactures of the district. The exhibition will consist of three distinct divisions—a manufacturers' department, an artisans' department, and a loan department. The guarantee fund asked for by the promoters of the exhibition is £2,000, of which about one-third was guaranteed by the meeting, and a considerable portion of the remainder promised.

PNEUMATIC APPLICATION OF AMMONIACAL GAS.—M. C. Tellier, whose proposed application of ammoniacal gas to locomotion was recorded in the *Journal* of the Society a short time since, now suggests a more simple application of the same substance, that of using it to create a vacuum, or partial vacuum, for industrial purposes, such for instance as the emptying of cesspools. The method proposed to be employed is to fill an iron receiver with the gas in question, and convey it to the spot where the vacuum is required. At the upper part of the receiver is a small reservoir containing water, and which communicates with the interior of the receiver by means of a stopcock; when this is opened the water rapidly absorbs the gas, and the required vacuum is obtained. The quantity of water necessary for this purpose is said to be in the proportion of six or seven litres to a cubic metre of gas. In order not to lose the ammonia this is allowed to escape into another similar reservoir at the lower end of the receiver before the connection is opened between the interior of the latter and the cesspool. With this arrangement the total cost, in addition to that of the apparatus and the original supply of ammonia, would, according to M. Tellier, be reduced to the value of the coal required to disengage the gas from the solution, and this he estimates at four or five centimes the cubic metre. M. Tellier contemplates many applications of this principle, but the above will sufficiently illustrate his views.

TRANSFORMATION OF NAPHTHALENE INTO BENZOIC ACID.—Two French chemists, brothers, announce the following method of transforming the residuum naphthalene into benzoic acid. In the first place the naphthalene is transformed into thallic acid, and afterwards into thallate of lime, and the latter is converted by heat into benzoic acid and carbonate of lime. The acid derived from naphthalene has the same unpleasant odour as that obtained from the urine of herbivorous animals, and it is conjectured therefore that the agreeable odour of the same substance when derived from the gum is not normal but due to the presence of some foreign substance.

LIQUID GLUE.—The use of this substance has become very extensive in France, and it may be useful to give the process by which it is obtained. A kilogramme, 2½ lbs. avoidupois, of good glue of Cologne, or Givet, is dissolved in a litre of water in an earthen pot plunged in hot water, the water lost by evaporation being replaced. When the glue is completely dissolved, one fifth of a kilogramme of nitric acid at 80° centigrade is added; the acid throws the solution into a violent state of effervescence, and a quantity of reddish coloured gas escapes. When the mixture has become quiescent it should be well stirred, set aside to cool, and afterwards placed in well stopped vessels for future use.

METALLIC CEILING.—While all other departments in the internal decoration of houses have kept pace with improvements in other branches of industry, it is a somewhat remarkable fact, and one that has long engaged the

attention of architects, that the ceilings of our rooms, with their unseemly blisters and network of cracks, are still, generally speaking, just what they were many years ago. Mr. Little has invented a system for the construction of ceilings, which consists in the application to the joisting of very thin stamped ductile metal, in ornamental embossed panels of such sizes and shapes as may be required. These stamped panels are fitted for every kind of decoration in colour, and if inserted as plain surfaces, may be used as the ground for every description of cartoon painting, combining with lightness and durability artistic and ornamental effect at a comparatively small cost. Besides its applicability to the ceilings of rooms, and all public buildings, churches, &c., the system may be made use of with the same effect in staircases, halls, and porticoes, and even on the walls of rooms. It affords the means, when coupled with an iron framing, of making theatres fire-proof, thus avoiding those sad contingencies to which these crowded buildings are so exposed.

Commerce.

SPIRITS AND WINE CONSUMPTION.—The average consumption of spirits, per head of the population, is shown by the following figures, for the last 60 years:—

	GREAT BRITAIN.		IRELAND.	
	Foreign and Colonial.	Home-made.	Foreign and Colonial.	Home-made.
1800	Gallons. 0-31	Gallons. 0-531	Gallons. 0-09	Gallons. 0-257
1820	0-24	0-440	0-05	0-490
1840	0-22	0-787	0-04	0-907
1860	0-21	0-724	0-03	0-808

The wine consumption shows a gradual decline, which is not compensated by any very apparent increase in malt:—

	GREAT BRITAIN.	IRELAND.
	Gallons.	Gallons.
1800	0-46	0-28
1820	0-33	0-07
1840	0-34	0-09
1860	0-27	0-09

COTTON IN SIAM.—The *London and China Telegraph* says that special efforts have been made to increase the supply of cotton for the coming season. The profits to the cultivators on this important staple for the past two years have stimulated the people to give it greater attention, but with every possible effort it is not probable the increase can add more than one-fifth to the last crop. The cultivators are too few to expect more than that. According to the custom-house returns, 17,710 piculs have been exported during the year from Bangkok up to the 14th November, amounting to 2,334,339 lbs., and worth, at a moderate estimate, say 500,000 dols. The season (in mercantile language) is now over, but it is possible that the whole export for the year may reach 18,000 piculs.

BEET ROOT SUGAR IN FRANCE.—The beetroot sugar manufactured in France in September last amounted to 2,755,400 kilogrammes, in October to 38,847,910, in November to 44,832,875, in December to 35,476,845, and in January to 13,474,652, making for the five months 135,387,682 kilogrammes. Of this the sugar manufactories in the department of the North produced 50,618,237 kilogrammes, in the Pas de Calais 23,467,933 kilogrammes, in the Aisne 21,860,699, in the Somme 13,152,597, in the Oise 10,628,696, and in other departments 15,659,550 kilogrammes. There remained, moreover, in store of the

preceding year's produce 18,828,243 kilogrammes. The consumption of beetroot sugar during the same five months amounted to 189,160,908 kilogrammes. The stock of beetroot sugar on the 31st of January last amounted to 87,470,079 kilogrammes, being 18,753,787 kilogrammes more than on the corresponding date of the year 1864. The number of sugar manufactories at present at work is 398, being 34 more than at this time last year. These returns are regarded as indicating that the beetroot sugar manufacture in France is prosperous.

THE VINE IN ALGERIA.—This cultivation has made great progress within these last few years. In the year 1862, the land planted with vines was estimated at 16,000 acres, of which 8,000 are situated in the provinces of Algiers, 5,500 in the province of Oran, and 1,500 in the province of Constantine. The vineyards produced in that year 43,222 hectolitres of wine, and 18,472,912 lbs. of grapes were sold for the table. The land was chiefly planted with the Chasselas-Burgundy, Alicante, and Grenache vines. In 1863 additional plantations were made, both by the Arabs and colonists. The number of planters amounted to 27,281, of whom 22,300 were natives, and 5,000 Europeans. The vineyards covered 87,000 acres, of which 50,008 were planted with vines producing black, and the remainder with those producing white grapes. Of these vineyards, 10,500 acres are situated in the province of Algeria, which produced 83,000 hectolitres of wine, and 8,500,000 lbs. weight of grapes for sale; 64,000 acres in the province of Constantine, producing 80,000 hectolitres of wine, and 4,100,000 lbs. of grapes; and 12,500 acres in the province of Oran, producing 20,000 hectolitres of wine, and 2,000,000 lbs. of grapes. The vines in the province of Constantine are newly planted, and do not as yet produce much wine.

EGGS.—From a recent Parliamentary return it appears that the annual importation of eggs into this country is at the rate of near one million daily.

COTTON SUPPLY.—The largest amount of cotton brought into this country for consumption was in 1860, when it amounted to 2,650,000 bales of 400 lbs. each. The total imports in Liverpool in 1864 were 2,247,755 bales, of which rather more than one-half were from India.

Colonies.

NATAL.—Of late years the coast lands of this dependency have been steadily opened up for the cultivation of sugar cane, coffee, tobacco, and other tropical products. The county of Victoria is separated from the seaport of Durban by the river Umgeni, which, although shallow enough during the dry winter months, is in the summer so deep and dangerous that it has been a formidable obstacle to traffic. While production and traffic were alike small the inconvenience entailed by such a troublesome stream was not felt to any material extent. In ten years, however, a great change has come over the country. There are now thirty sugar mills driven by steam at work in the colony. Last year about 4,000 tons of sugar were produced. Coffee and other plantations are springing up in all directions, and the Cotton Plantation Company has nearly 1,000 acres under cultivation. Hence has arisen the necessity for a bridge over the Umgeni, and the Queen's-bridge, which was recently opened, is an iron girder bridge, erected on cylinders, which rest on a bed of crosscut timber piling. There are seven spans, of about 100 feet wide each, and the bridge with its approaches is altogether about 1,100 feet long. The roadway is 20 feet wide and paved with asphalt. No other bridge in South Africa can at all vie with this either in size or appearance, and it is creditable to the young colony that it should have been accomplished, at a cost to itself of about £17,000, what the older provinces of the Cape have not yet contemplated.

NORTH AUSTRALIA.—An Australian paper says:—"If a colony could be established by Government *employés*, there would be no doubt as to the success of North Australia. It appears that many hundreds of young men, belonging chiefly to the middle class of this community, are quite ready to colonise the new country for the remuneration of five shillings per day. For this pay they are willing to bind themselves as labourers to do the rough work of the settlement in spite of aboriginal Malays, alligators, and tropical summers. This shows that the love of adventure is as strong here as in other parts of the world. Whilst, however, the two Government expeditions which have sailed are absolutely necessary to the establishment of the young colony, it must be borne in mind by the hundreds of persons who are looking with interest to North Australia, that the success of the enterprise must, after all, depend upon the efforts of individuals who go to occupy the country upon their own responsibility. A large extent of land has been sold, and it is fair to suppose that at least some of the purchasers will either become settlers themselves or will cause their property to be occupied by others. It is not to be expected that South Australia should supply the new country with any large number of settlers in addition to those who go there in the pay of the Government. In fact, the bulk of a population like ours would be as much out of place in North Australia as in India. Our labourers would be unsuited to the wet tropical summers of such a country, and would be unable to compete with the coolies and the Chinese who will come in thousands as soon as there are planters and other settlers ready to make arrangements for their immigration. But there is a way in which this colony could materially assist the new colony, that is, by persevering in the attempt to send stock overland. If this were successfully done, North Australia would almost immediately secure an export trade with Madras, Calcutta, Java, and Mauritius. The two last-mentioned countries are always ready to import horned cattle, whilst the Indian markets at the present time have to be supplied with horses from New South Wales and South Australia. The passage from North Australia to Madras or Calcutta would occupy about four weeks, and it is said that the vessels best suited to the trade would be those of about 300 or 350 tons burthen. September would be the proper time to ship horses for India, as they would then arrive there at the commencement of the cool season."

BARRADOES.—The shipments of produce last year were 36,106 hhds. sugar and 16,000 puns. molasses, against 42,000 hhds. sugar and 15,000 puns. molasses of the previous year. The cotton speculators also have cause to be satisfied, as their harvest, it is calculated, will realise 300,000 dols. return to the proprietors; and, what is more consoling again, this sum will be sure to be circulated in the island, the cotton being grown on small properties and sold on the spot. Here is no little advantage to reap from about 2,000 acres of land which hitherto were almost waste, giving little or no return. The sugar crop, this year, it is anticipated by some (of course the most sanguine) will reach 50,000 hhds. A steam plough has been successfully used on one estate, and the canes grown on this land are said to be of so superior a quality as to yield some three hogsheads to the acre.

BRITISH GUIANA.—The quantities of produce shipped from the whole colony during the past year are as follows:—Sugar, 73,312 hhds.; rum, 26,063 puns.; molasses, 12,632 casks; timber, 816,812 feet; and cotton, 239 bales. The quantities shipped in 1863 were 77,105 hhds. sugar, 80,252 puns. rum, 5,704 casks of molasses, 408,769 feet timber, and 52 bales of cotton. There is an apparent falling off in the yield of sugar and rum as compared with the previous year's returns, but it is only apparent. The crop of last year largely exceeds that of the previous year, but from the want of shipping there is a large quantity of produce lying on hand; in fact, a larger quantity than has been found on hand at the same period in any pre-

vious year, and it will have to be brought into the current year's exports.

PUBLIC WORKS IN NEW SOUTH WALES.—The opening of a branch railway from Blacktown to Windsor and Richmond, which took place on the 29th November last, was an event of much importance, not only on account of the benefit it has conferred upon a populous and fertile district, but also in relation to the question of railway communication in the colony. In order to lessen the cost of this railway, the works are much lighter in their character than those on the trunk lines. Should the new railway realise the expectations that have been indulged in, as to the suitability of the works to the nature of the traffic, the experience gained may be of value in the construction of future lines.—At Newcastle, progress is being made with the various works for the improvement of the harbour. The northern breakwater is being proceeded with; upwards of 1,200 tons of stone were deposited in November last. The ballast is supplied by vessels coaling at the port. Preparations are being made for the repair of the southern breakwater, which was damaged by gales. Along the greater portion of the new wharf the water has been deepened, and vessels drawing seventeen or eighteen feet of water can now go alongside. The steamers' wharf is completed, and plans are being prepared for a commodious goods shed to be erected close to it.

SALMON AND TROUT IN TASMANIA.—A favourable account has been received of the progress of both the salmon and trout in Tasmania, and Badger Creek, the locality chosen, appears admirably adapted for the salmon. The fish at present there are in good health and growing fast. The advisability of constructing a regular fish-hatching establishment at the place has been dismissed.

Publications Issued.

LE MONDE DE LA MER. By "Alfred Frédo." Royal 8vo. Paris (*Hachette*).

LE CIEL. By Amedée Guillemin, and

LES PLANTES. By Louis Figuier (same form and same publishers).

LE MONDE DES INSECTES. By S. Henri Berthoud. Royal 8vo. Paris (*Garnier, Freres*).

These represent a class of work which has only lately sprung up in France—popular expositions of scientific subjects, profusely illustrated. The most remarkable of the four whose titles are given above, is that which stands at the head. It is not signed by its author, but was the work of the late Moquin Tandon, of the Institut, a naturalist whose name would have stamped it with authority, but being written in a popular style, and not in scientific form, the academicians used the pseudonym which he had often affixed to poetry and other miscellaneous works. He died while the sheets were going through the press. The work in question occupies more than six hundred pages, and all the products of the sea and its banks, from seaweed to white bears, are treated of in turn, and in a very interesting manner—scientific facts being intermingled with amusing anecdotes and remarks, and sometimes, it must be admitted, not quite according to English notions. The illustrations consist of twenty-one full-sized chromo-lithographic plates, and two hundred illustrative cuts, of all sizes, on wood—all from the pencil of M. P. Lackertbauer. These latter are executed with great care and distinctness, and the peculiarities of the sea anemones and of the microscopic creatures of the ocean are given with rare fidelity; but the twenty-one coloured plates are really exquisite. M. Moquin Tandon's last work may not increase his high scientific reputation, but it will assuredly make his name known to thousands who never heard of it before, and would not otherwise have easily become acquainted with the wondrous creatures which he so lovingly and so agreeably describes.

The second book on the list is also a popular production by a highly scientific man, and, so far as the subject admits of it, it is illustrated with the same careful and profuse elegance. Like the preceding, the subject is treated with as great avoidance of technicalities as possible. Both these gentlemen acknowledge the assistance of their brother savants in various countries, and it is gratifying to see the names of Herschel, Gossé, and other Englishmen in the list. The other two treatises are by gentlemen well known as popularizers of science and pleasing writers, and they have performed their work in a very conscientious and agreeable manner. It would not be easy to find four other books in which knowledge is conveyed in a more pleasing style, or four volumes presenting higher qualities as regards typography and illustration.

Notes.

SOUTHERN COUNTIES ASSOCIATION FOR THE ENCOURAGEMENT OF AGRICULTURE, ARTS, SCIENCE, MANUFACTURES, AND COMMERCE.—The second monthly meeting of the Council of the Association was held on the 7th inst., at the house of the Society of Arts. Present—the Marquis Camden (in the chair), Lord Viscount Sydney, Lord Viscount Eversley, Sir Henry Mildmay, Bart., G. Cubitt, Esq., M.P., G. Lyall, Esq., M.P., Lieut.-Col. Lennard, C. Wykeham Martin, Esq., Hon. and Rev. S. Best, Rev. J. Clutterbuck, and Messrs. Clutton, Spiers, Rigden, Whitehead, Simonds, Middleton, and Newton. After the transaction of the general business of the Council, the offer of the services of G. W. H. Stute, Esq., of Yateley, as secretary, were accepted. Sir W. Brook Bridges, Bart., M.P., and Major-Gen. the Hon. A. Hood were elected vice-presidents; and Wm. Deedes, Esq., of Sandling Castle, Wm. Wells, Esq., of Redleaf, Peasbush, and the Rev. John Goring, and P. S. Punnett, Esq., of Chart Sutton, added to the Council. A code of bye-laws was referred to a sub-committee, consisting of Lord Viscount Eversley, Colonel Lennard, Mr. Lyall, and Mr. Rigden, to report to the next meeting of the Council. After much consideration it was resolved that it would be impossible, before June, 1865, to make the necessary arrangements for the great annual exhibition of stock and implements proposed by the Association, but that the meetings for the second, third, fourth, and fifth departments of the Association—viz., natural history, local geology, botany, and horticulture, the second; the arts, manufactures, and commerce, as developed in these six counties, the third; local history and archaeology, the fourth; and the improvement of the dwellings and the general condition of the labouring classes, the fifth—shall be held, and the times and places determined at the next Council. The Council was then adjourned to Wednesday, April 5, at two o'clock.

RENEWAL OF OLD FRUIT TREES.—A French horticulturist has hit upon a curious mode of revivifying old fruit trees. He recommends that so long as the roots of the old trees are sound they should never be destroyed. His plan is, when the tree ceases to be productive, to cut it down to the neck of the roots and to insert two, three, or four grafts into the stump. This system he declares applicable to pear, apple, cherry, and almond trees. When the grafts have been put in, the face of the stump must be carefully covered with grafting wax or clay, and then the whole surrounded and covered up with mould, so that only one or two eyes of the grafts may be exposed. Six old pear trees were so treated on the 18th of March last; the grafts have attained from thirty to sixty inches in length, look very promising, and are expected to bear a good crop of fruit in three years. Where the roots of an old tree are well developed and sound, this mode of making use of them for a new family of small trees is certainly worth a trial.

BROME.—M. A. Lavallée, who has given much attention to the cultivation of the *Bromus schraderi* (referred to recently in the *Journal*), has just published a pamphlet on the subject,* giving an account of the experiences of himself and others with regard to this plant, its mode of cultivation, yield, influence in the production of milk, and chemical analysis. The main facts given are as follows:—The plant will yield two crops a year at first, and, in some cases, after the first year, three crops. A sandy soil seems best adapted for producing the grain of the plant; on damp land the seed is less abundant, small, and lighter. The yield, in some instances given, was as 74 to 1. The grain is exceedingly light, weighing little more than about two pounds to the gallon, or about half the weight of oats. After the sowing the ground is said to require no care whatever but simple rolling in spring. The soil should be turned up to a good depth previous to and heavily rolled after sowing; the latter point being much insisted on. If sown in March or April the first green crop may be cut in two months. The brome kills all the weeds that spring up with it. It is said to be the thickest-growing and cleanest crop known. The duration of the plant cannot yet be fixed, some in France are five years old, and are said to give no sign of failure, although five crops a year have been taken off it.

CLIMATE OF ENGLAND.—At the Meteorological Society, Mr. Glaisher recently read a paper, in which he stated that the results of recorded observation showed that the character of the climate at the end of the last century was certainly very different from what it is now. Long continuance of frosts, and frequent and heavy falls of snow, are facts which can be recorded without instruments as well as with them. In the early period they were of more frequent occurrence than in the middle period of 30 years, and far more so than in the latest period. Thus the result, as formed by this comparison, without reference to instruments, and every investigation made all tend to confirm the accuracy of the indication found by instruments, viz., that our climate in the last hundred years has altered; that the temperature of the year is 2° warmer now than it was then; that in the month of January it is still higher; that the winter months are all much warmer; and that every month in the year seems to be somewhat warmer than before. The author remarked that this result was indeed important, if true, and he could not see how it was otherwise than true. Its effects will be to influence agricultural produce. New fruits may be introduced with advantage, and the character of our people will be altered.

EDUCATION IN RUSSIA.—The Russian government, as a consequence of the emancipation of the peasants, has taken measures for the diffusion of instruction among the agricultural population. An additional budget of 450,000 roubles for the year 1865 has been decreed, so that the budget of Public Instruction now amounts to about 1,800,000 roubles. This supplementary budget provides for the founding of village schools, of eleven new gymnasia (colleges), for the purchase of books, paper, &c., for the poorer peasants, for supplementary payment to schoolmasters and professors, for the purchase of scientific instruments, for the establishment of laboratories and museums, for the reorganization of the University of Warsaw, for the foundation of a Polytechnic School, and for other schools for teaching agriculture and horticulture.

GRANTS OF PROVISIONAL PROTECTION.

- Aeriform fluids, motive power from—501—M. P. W. Boulton.
 Beer, &c., brewing, fermenting, &c.—2718—C. Garton and T. Hill.
 Bottles, jars, &c., stoppers for—27—N. Thompson.
 Buoys, beacons, &c.—387—C. Atherton and A. H. Renton.
 Cabinet, sofa, and chair-bedsteads—476—A. Sharp.
 Caoutchouc, manufacture of—398—P. A. Le Comte de Fontaine-Meyre.
 Coats and capes, waterproof—471—C. D. Barge and A. Hermant.
 Dough, apparatus for working—483—J. H. Johnson.
 Escapement, application to clocks of a circular—462—P. E. Bidaut.
 Filtering apparatus—249—V. Burg.
 Fire-arms—425—B. Thompson.
 Fluids, apparatus for raising and forcing—410—J. Gresham.
 Furnaces—443—E. B. Wilson.
 Globes or shades—2791—M. A. F. Mennons.
 Hay, cotton, &c., construction of presses for—3294—H. A. Bonnerville.
 Iron, machinery for rolling and hammering—376—J. Ramsbottom.
 Lawn mowing machines—458—J. B. Brown.
 Liquids, obtaining power from—2770—C. Garton.
 Looms—494—J. Dodgeon, J. Gaukröger, and W. Shackleton.
 Mashing machines—481—R. Willison.
 Mineral oils, extracting gases from—344—W. Sim.
 Motor, mercuro hydraulic—492—R. A. Brooman.
 Ordnance, &c., manufacture of—295—J. H. Johnson.
 Puddling furnaces—473—J. G. N. Alleyne.
 Reaping machines—384—D. H. Barber.
 Shifting wrenches—467—W. Clark.
 Ships' shafts, examining, cleaning, and repairing the bottoms of—106—R. F. Moll.
 Steam engines—338—C. Lunelley.
 Stopping bottles—464—J. J. Childley.
 Tanning leather—2704—W. Smith.
 Ventilating bilids—443—C. Lungley.
 Weights, use of magnets in overhauling—461—T. P. Tregakis.
 Zinc, products obtained when coating iron with—469—J. Graham.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

- Crinolines, covered steel for—588—W. S. Thomson.
 Clothing, covered springs for—623—T. S. Sperry.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MARCH 29.—"On Window Horticulture, and the Cultivation of Plants and Flowers in Cities and Crowded Localities." By JOHN BELL, Esq.

APRIL 5.—"On food for Cattle." By Professor JOHN COLEMAN.

CANTOR LECTURES.

The Third Course for the present Session will consist of six Lectures "On Some of the Most Important Chemical Discoveries made within the last Two Years," to be delivered by Dr. F. F. GRACE CALVERT, F.R.S., F.C.S. (Corresponding Member of the Royal Academy of Turin; of the Société Industrielle de Mulhouse; of the Société Imperiale de Pharmacie de Paris, &c.), on Tuesday evenings, at Eight o'clock, as follows:—

APRIL 4TH.—LECTURE 1.—On the discoveries in Chemistry applied to Arts and Manufactures.

APRIL 18TH.—LECTURE 2.—On the Discoveries in Chemistry applied to Arts and Manufactures (*continued*).

APRIL 25TH.—LECTURE 3.—On the Discoveries in Agricultural Chemistry.

MAY 2ND.—LECTURE 4.—On the Discoveries in Physiological Chemistry.

MAY 9TH.—LECTURE 5.—On the Discoveries in the Chemistry of Rocks and Minerals.

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

INSTITUTION.

The following Institution has been received into Union since the last announcement:—

Carmarthen, Literary and Scientific Institution.

Proceedings of the Society.

SIXTEENTH ORDINARY MEETING.

Wednesday, March 22nd, 1865; Dr. W. A. MILLER, F.R.S., Professor of Chemistry, King's College, London, in the chair.

The following candidates were proposed for election as members of the Society:—

Booth, Captain John, 21, Kensington-crescent, W., and Conservative Club, S.W.
Chatwood, Samuel, Lancashire Safe and Lock Works, Bolton.

Good, Henry, 21, Upper Hamilton-terrace, N.W.
Mackenzie, James Joseph, Jennings' Hotel, Albemarle-street, W.

Morris, William, Carmarthen.
Scully, George, 4 and 5, Agar-street, and 7, Adam-street, Strand, W.C.

The following candidates were balloted for and duly elected members of the Society:—

Newcombe, Cornelius Prout, 16, Barnsbury-villas, Liverpool-road, N.

Perkes, Samuel, West Dulwich, S.

Scott, Colonel, R.E., Ealing, W.

Tanqueray, Arthur Charles, Hendon, Middlesex, N.W.

The Paper read was—

ON THE PRESERVATION OF FOOD, ESPECIALLY FRESH MEAT AND FISH, AND THE BEST FORM FOR IMPORT AND PROVISIONING ARMIES, SHIPS, AND EXPEDITIONS.

By G. C. STREET, Esq., F.R.C.S.

The increased and increasing cost of meat in this country has recently given a fresh impulse to the important question of the preservation of food of all kinds, whether as an article of import for home use, for providing stores for the army, navy, or merchant service, or for expeditions, &c. The recent correspondence in the public journals, excited by the introduction of the South American beef as a means of meeting the deficient supply of fresh food at home, has also given a new impetus to the very important question, By what means can provisions, when and where in great plenty, be preserved against a season

of great dearth or pressing necessity? This question has frequently occupied men's minds, either as a commercial speculation or as a useful and benevolent object, and many processes have been advocated and used for this end. In the subsequent remarks I am about to make I shall confine myself almost entirely to the means used for the preservation of flesh food.

The first means, one that may well be styled the "ready method," and which has been the one longest in use, is to prevent decomposition by certain saline substances; common salt, as the most abundant and cheapest, has been most frequently used; to this has been added other salines, such as nitrate of potash and chloride of aluminium, or certain aromatics, as pepper and spices; with these have been variously combined sugar, vinegar, wood naphtha, &c.,. A patent was taken out in 1847 for using a preservative liquid made by neutralising strong acetic acid by sesquicarbonate of ammonia; the result is "acetate of ammonia, which is eminently volatile, and is given off in the act of cooking." This saline was, however, to be mixed with common salt. The ready method has been long applied to the preservation of fish, and a very large trade has been carried on both in import and export. An instance of the former may be given in the introduction into this country of the herrings cured by the Dutch, in which trade we could not compete with them after many attempts, and with much support to the manufacture by grants and supplies voted by Government, the Dutch excelling us by the care with which they conducted the process. An instance of export may be taken from the great quantities of pilchards which are cured and packed in casks and sent to the inhabitants of the European shores of the Mediterranean. Government formerly made grants in aid of this trade. The means for imbuing the substance to be preserved with the saline matters are various; the commonest is rubbing with dry salt, and thus introducing it by capillary attraction or endosmosis, at the same time that much of the fluid constituents of the meat are abstracted. Soaking in brines, differently compounded, is another plan. This would, however, abstract from the flesh the same fluids. Other processes, which partake of a less crude but more scientific feature, are the patent of C. Payne, 1840, in which an apparatus is suggested "on the principle of the ordinary air-pump," to exhaust the air from the chambers, and, at the same time, from the structures of the meat, and the addition of a force-pump for "supplying the liquor" for salting. This is a plan similar to Kyan's method for preserving wood against decay. S. Carson's patent of 1842 mentions four methods—(a) injection; (b) exhaustion of any gases in the meat, and consequent penetration of pickling liquids by atmospheric pressure; (c) "causing preservative liquids to penetrate more quickly into meat or animal substances by means of pressure produced by centrifugal force;" and (d) the same object gained "by means of a weight of liquid in motion being suddenly checked or stopped."

A still more interesting process, and one that is evidently the most expeditious and most readily used, is that of injecting the carcass of an animal recently killed with a solution of such saline compounds as may be thought best adapted for the purpose. I allude to the plan advocated and practised so successfully by Mr. Morgan, who read a paper on the subject before this Society in April, 1864. Some plans of a similar character were, however, propounded some time before. It does not appear with what success. They are as follows:—In 1834 a patent was granted for "injecting certain antiputrescent and flavouring preparations into the blood vessels of animals by means of a force-pump." The preparations may consist of water, salt, maitpetre, spice, and vinegar. Another, in 1851, for injecting the carcasses of animals with a saline liquid containing chloride of aluminium, chloride of sodium, and nitrate of potash; it does not, however, explain that the fluid is injected by means of the blood vessels. In 1855

a method for "Preserving and curing by salting the flesh and hides of animals in an entire state by injection, by preparing a solution of saline substances, to be forced into the veins and arteries of animals within a short period after they are slaughtered, so as to render them incapable of becoming putrid." It will only be necessary to state that the preservative matters used by Mr. Morgan are salt, nitre, sugar, with spice and sauce for flavour, a small quantity of mono-phosphoric acid being added to coagulate the albumen contained in the fluids of the flesh; and that these substances are injected in solution by gravitation through the main artery of the body, and thus to all its minutest ramifications, returning by the veins to the right side of the heart; it must be manifest that by this means every part and every structure of the body must be completely permeated by the solution, and therefore thoroughly and effectively influenced by the antiseptic properties of the substances injected. This plan for curing meat was adopted by the Admiralty for experimental purposes. Animals were salted, cut up, several joints dried, and sent abroad in ships, to ascertain by the tests of time, climate, packing, &c., what effects would be produced on them.

Mr. Morgan's method has been objected to on the ground that it is a most effectual means of abstracting from the flesh its nutritious qualities, and to a much greater extent than by the ordinary plan of salting by rubbing with dry salt. I applied to Mr. Morgan for the results of the experiments above mentioned, and have been informed that he has received two consignments of meat from South America in small quantities as samples, but not enough to be introduced for sale. He has had notice from the Admiralty that the meats prepared last January twelvemonth and sent abroad were all sound and right; the dried meat, manufactured at the same time, was reported on by a Commission of the Channel Fleet this autumn, and pronounced good and agreeable. He has also heard from the French Government that the meats, beef and mutton, prepared in July and August, 1864, when examined in January, 1865, were found perfect. The features of his plan are, 1st, the supplying meat as perfect as fresh, also with vegetable products added, as sugar, potash, &c., and, therefore, even better than fresh meat; 2nd, that its bulk is diminished from one-half to two-thirds, and it is therefore more portable; 3rd, that in the preparation any desired antiseptic can be added; 4th, the hide is cured at the same time as the carcase.

The process of the "British Meat Preserver Company" is allied to the salting method. A powder is dissolved in water, the meat is dipped in the solution, and afterwards dried. The solution has the property of restoring meat that is already tainted. By whatever process meat or fish may be salted it can be dried in the open air or in the drying rooms, or packed wet in casks in the ordinary way.

The second class of methods is that of drying. This is accomplished by currents of ordinary air, by air deprived of moisture by chloride of calcium or by passing over sulphuric acid. Chilled air is prescribed sometimes; at others hot air, and air at 138°. Some advocate complete, while many think that partial, drying is sufficient, to the extent of from 50 to 80 per cent. of the moisture. When thus much of the process is completed the joints are to be varnished with a strong solution of gelatine, or packed in boxes by pressure, the interstices filled with "concentrated liquor," the lids to be soldered on, and the whole submitted to a temperature sufficiently high to produce steam in the box. Various varnishes for covering the substances to be preserved have been advocated. These consist of gelatine, glycerine, treacle, elaines, oils, and even collodion, or dipping the provision into a thin cream of plaster of Paris, which, when set, is to be saturated with melted wax, suet, &c. More recently several other plans for coating meat, raw or cooked, have been propounded, such as covering the joint with gelatine, and then treating with oak bark, or

acetate of alumina, so as to form a coating of leather. Gutta percha in solution has been recommended also.

The third class is that of cooking the food to be preserved, either before or after being placed in the vessel containing it. In the first case one plan is that the cooked meat is to be put into wooden vessels, and extract of meat is poured over it, "in such a fusible state as to find its way into every vacuum." Another: flesh, fish, fowls, or vegetables, fully cooked, packed with hot fat or jelly, the vessels not to be heated after their apertures are closed. The preparation of essence of meat, concentrated soups, *Soyer's osmazone* food come under this head. The process of most interest and most commonly practised is that of cooking the food in the vessel in which it is to be kept. The meat, fish, poultry, game, or whatever is to be preserved, is introduced into a tin cylinder of convenient size, the top soldered on, and a small hole made in it for the escape of air and the steam generated during the cooking. These canisters are placed side by side in a bath containing a solution of chloride of calcium; heat is applied, and the temperature raised to between 250° and 280° . At the proper time, when the food is fully cooked and all the atmospheric air driven out, a morsel of solder is applied to the pin-hole, and the process is substantially complete. This is by far the commonest system of preserving fresh meat food of all descriptions, and in almost every form—soups, stews, boiled food, hashes, variously prepared, with the addition of vegetables, sauces, or other flavouring substances. There appears a difficulty about roasted joints, game, or fowls, which is provided for in this way:—The meat or poultry is cooked by being plunged into boiling fat for the necessary time; it is afterwards preserved in the tins in the usual way, with the addition of a little stock by way of gravy, or by being surrounded with fat. The cases are then cleansed, painted, to preserve the tin plate of which they are composed, and removed to a proving room, where they remain for a week or ten days, exposed to a temperature of about 90° ; if the process has not been effective for the expulsion of all free oxygen, decomposition takes place, and instead of the ends of the canister exhibiting an indented form, they bulge out, on account of the new gases formed in the case by the putrefactive process. Such samples are, of course, condemned. If, however, they stand this test, they are conveyed to store-rooms for future use. A variety of this plan has been introduced by Messrs. McCall. After the meat, say a piece of beef, weighing 6lb., has been introduced into the tin, the lid—which has on its under or internal surface a small tin chamber having two pin-holes plugged up with a fusible metal, which melts at a temperature in excess of 212° , and containing a little block of sulphite of potash—is soldered down, a small vent only being left open; this is placed in the chloride of calcium bath at boiling heat; here it is cooked for three hours; when the operator considers the meat to be done, he solders up the pin-hole, thereby hermetically sealing the case. The heat of the bath is subsequently raised to about 270° for from 35 to 40 minutes; this increased temperature has the effect of melting the fusible metal plugs; the sulphite escapes into the case, absorbs any oxygen which may be present in it, and then mixes with the food.

I just mention, and pass over a means of preserving food from decay, by freezing or storing it in ice-houses, which can be only applicable under certain circumstances, as in camps, or when an army engaged in war has taken up winter quarters, or during a continued siege, &c. Food is thus preserved in Canada during the winter.

The knowledge that atmospheric air, or rather the oxygen contained in it, is the prime inciter to and supporter of decomposition, at once pointed out that it would be only necessary to get rid of this gas to arrest or entirely prevent the resolution of the aliment sought to be preserved. The means applicable for this end may form a fourth class. The principal are the following:—In 1810, Augustus de Reims took out a patent for applying "known principles to preserve animal food and other perishable articles a long

time from perishing or becoming useless." The preserving vessels may be made of iron, glass, or any other metal, or of earthenware strong enough to withstand the pressure of the atmosphere when exhausted. In the lid there is a "protuberance, wherein a valve is fitted, that will let the air escape out of the vessel, but not suffer it to come in." It is exhausted by a particular exhausting machine. "The process with the common air pump" is said to be "tedious, and not to be relied on." The patent of John Bevan, in 1842, is for exhausting from the containing vessels all the air, by connecting the cases with a vacuum chamber on the one hand, and with a vessel holding gelatine or other suitable material on the other hand, in such manner that by opening the communications the air escapes into the exhausting apparatus, while the gelatine succeeds to supply its place. Again, in 1853 Alex. Robertson recommends his process, whereby the provisions are placed in a suitable vessel, with a "valve or door, opening on a hinge, and ground into its seat, so as to fit air-tight." The provisions are placed in it, the door is closed, and the air is then exhausted from it by means of an air-pump. An invention in 1855 was for "certain new and useful apparatus for exhausting, by means of a pump, and closing vessels in which vegetable or animal substances are to be preserved or improved by being placed in a perfect vacuum."

The fifth and last class of processes I shall mention appears to me the most important, as they fulfil more or less perfectly the requirements needed for the absolute expulsion of all atmospheric oxygen, and at the same time the substitution of a new atmosphere, composed variously of preservative gases, of course to the total exclusion of free oxygen. The first process having this object in view was patented in 1836. "The meat, raw or partly cooked, must remain in a mixture of salt and nitre" for a given time, "then be placed in tin cases filled up with brine, and turned over a vat of the same liquid, to introduce carbonic acid gas, for which purpose a pump may be used, or the gas may flow by a tube." Instead of making a vacuum by an air-pump, a small bag of nails, or iron filings, must be placed in the upper part of the vessels; the air will then be deprived of its oxygen. In the same patent other gases are mentioned as useful, "such as deutoxide of azote, hydrogen, and azote; other patents recommend the adoption of various compounds, such as carbonic acid gas, with hydrochloric or pyroligneous acids; sulphurous acid, in the form of gas and in solution; the vapour of alcohol, with or without carbonic acid; and "gaseous binoxide of nitrogen;" "nitrous acid gas and sulphurous acid gas, either alone or in combination." One of these, by Hippolyte Lamy, attracted much attention at the Paris Exposition in 1855. The title was "Certain improvements in preserving animal and vegetable substances;" and consisted in the introduction of sulphurous acid gas into the vessel containing the substance to be preserved; any acid taste engendered by this process was to be neutralised by a solution of baryta or bicarbonate of magnesia. I understand that this invention was not successful; that about 50 per cent. of the meat put up turned out bad. After several schemes and various composition of gases, all having for their object the absorption of atmospheric oxygen, had been tried, Messrs. Jones and Trevithick introduced a plan of, 1st, exhausting all, or very nearly all, the air from the chamber in which the meat to be preserved was placed; 2ndly, supplying the place of the air by pure nitrogen gas to nearly the capacity of the canister; and 3rdly, injecting a small measure of sulphurous acid gas. The rationale of this process consisted in getting rid of the oxygen by exhaustion to as great an extent as possible, and neutralising any that might remain either in the case, in the bone, or in the tissues of the meat. This is certainly a purely rational system of procedure, and only requires the proof of experience to mark it as excelling most, if not all, others, for it must, I think, recommend itself to all of us in that, if successful, it preserves to our use the meat, &c., in that fresh raw state most suitable for after cooking in any

way that may be deemed most desirable. It gives us also an opportunity of ascertaining the quality of the meat preserved. This none of the cooking processes can well accomplish. You may recollect in the Exhibition of 1862 there were some specimens—under the title of “Azotised raw meat,”—of fresh meat, salmon, &c., put up in glass cases; and I can well remember how anxiously I watched them from time to time, to see how the samples would bear the severe test of exposure to the heated atmosphere, and sometimes the sun's rays in that building. Not one example failed. Mr. Jones has kindly sent some samples prepared by his process, which are before us on the table, and a model which explains practically his method of putting up the provisions.

Since 1862, however, certain improvements in the preserving matters used, or in their application, have been effected. At the present time, the method of procedure is thus carried out. The gases to be used are previously prepared and tested as to their purity and usefulness; the cases are accurately made, so as to be air-tight, a small tube of flexible metal being placed in the bottom, and another in the top of the case. The meat to be preserved is then placed in the tin, and the top soldered down very securely; to the metal tubes are attached pieces of vulcanised india-rubber tubing; the cases thus prepared are then ready for the next step. The free ends of the elastic tubes are now attached to the extremities of metal pipes; by one the case is filled with water deprived of all free oxygen; this drives out all atmospheric air. The water is now shut off, and a stop-cock is opened, which admits nitrogen gas into the case, displacing in its turn the water it contained. Should it be thought desirable, thus much of the process can be repeated. The nitrogen that first filled the case is not wasted, but is conducted by a pipe into a spare gas holder for re-purification and future use; afterwards a measure of sulphurous acid gas is injected into the tin, proportionate to the space unoccupied by the meat; the quantity required is estimated, and is a matter of experience and calculation; then the flexible metal tubes are closed by being nipped, folded over, and soldered; the tin cases are then painted, labelled, and tested.

M. Pasteur's experiments go to prove that the germination of the spores of cryptogamic plants floating in the atmosphere may take place in an atmosphere destitute of oxygen, but this is very unlikely to occur when with the absence of oxygen there is the presence of sulphurous acid gas; the same remark will hold good with respect to the ova of vibriones, or other microscopic animals.

In describing this process it may appear complicated and tedious, as well as uncertain, but in actual practice it is not so; it is carried out with the greatest facility, and is the one above all others capable of the greatest despatch. The cost of the materials is very slight, and the expense of necessary plant certainly not greater than that of the cooked meat plan, while there is no necessity for furnace, steam heat, or engine.

As may be well seen by the beautiful specimen (a head of cauliflower in a glass case) on the table, vegetables may be preserved whole, fresh, and in their natural condition, without the slightest sign of decay, and with all the colour and freshness of a recent sample purchased in the market. The specimens of meat, consisting of a section of beef, mutton chop, &c., all under glass shades, give undoubted demonstration that this proceeding is certainly most efficient. The lean is unchanged in colour and consistence; the fat is free from any change, there is no appearance of rancidity or formation of adipocere; and they look as if just cut from the joint.

Having now given a résumé of certain processes for preserving meat, &c., it will be as well to glance at the chemistry of animal flesh, in order that we may more readily comprehend in what particulars these have attained or fallen short of their object.

In the living animal, the constituents of flesh and other structures are held together by the principle of life and constant renewal and repair; as soon, however, as life

ceases, these principles have a tendency to resolve themselves into new compounds by the union of their elements with atmospheric air and with one another. Raw flesh contains, according to Baron Liebig:—

76 to 79 per cent. of water.

2 „ 3 „ of soluble albumen.

17 „ 18 „ of fibrine and insoluble matters.

If a piece of flesh, recently cut from a joint, be placed upon a plate, a fluid begins to drain from it; this consists of water, holding in solution albumen, free lactic acid and salts of lactic, phosphoric and inosinic acids, with the alkaline bases of potash chiefly, with soda, lime, &c., and blood. This juice, which may be looked upon as the active principle of meat, may be obtained by cutting lean raw meat into pieces, bruising them in a mortar, pressing the pulped meat in a coarse cloth, so as to squeeze out as much as possible of the fluid parts; by repeating this process, with the addition of a small quantity of water and evaporating the liquid obtained, we get a true extract of meat, which is only $\frac{1}{2}$ nd part of the weight of the original mass. This means it can scarcely ever be necessary to carry out into practice, except, perhaps, in a few urgent medical cases, its very expense being a great objection, and the end gained not being equivalent to the trouble and cost. The juice of flesh is found to be very rich in the salts of potash, and to contain but small quantities of the salts of soda, while blood itself contains chiefly the salts of soda, and but a very small proportion of the salts of potash. In the ox, Liebig states that for every 100 parts of soda contained in the body there are 59 parts of potash in the blood, and as much as 279 parts in the flesh. Salting reduces the meat of young animals, which is rich in albumen, to the condition—more or less aggravated according to the extent to which it is carried—of the flesh of very old animals; by abstracting albumen the meat is rendered less rapid, the fibre is made drier, harder, and less digestible, and, for this, and coupled with the reason that the greater part of the nutritive element is abstracted, less fit for the animal economy. By the ordinary method of salting, the fluid and more soluble matters contained in flesh are abstracted and are most frequently wasted, the salting-trough or brine-tub being periodically emptied, cleaned, and fresh salt or brine made use of; and in the case of provisions packed in casks with brine, very many of the best constituents of the meat are abstracted, and finally thrown away.

The medical aspect of this subject is full of interest. It is well known that scurvy, a debilitating and fatal disease, is brought on by the use of a diet containing but very little potash, which we have noticed above to be a principal base of the salts contained in meat, and which is abstracted largely by the ordinary process of pickling. The evident remedy, and one which acts with magical efficacy, is the supply of the potash so much required by the animal economy, in the form of lemon juice, (as recommended so far back as 1780,) of sound potatoes, or other vegetables. At the time of the cotton distress and famine in Lancashire, when so many of the poor were compelled to live on a very moderate quantity of flesh food, and that principally in a salted condition, it providentially happened that the crop of potatoes was a very good one, and the price in consequence much lowered, thus enabling the poor, or those who provided the poor with food, to obtain this antiscorbutic vegetable at a more moderate rate. Baron Liebig has a paragraph very apt to this subject. He says, “It is obvious that, if flesh employed as food is again to become flesh in the body; if it is to retain the power of reproducing itself in its original condition, none of the constituents of raw flesh ought to be withdrawn from it during its preparation for food. If its composition be altered in any way—if one of the constituents which belong essentially to its constitution be removed, a corresponding variation must take place in the power of that piece of flesh to re-assume in the living body the original form and quality on which its properties in the living organism depend.”

The practice in use by the large contractors who supply stores for the Government and our merchant marine, is to cut up the carcase of the animal into pieces of 8lbs. for beef and 4lbs. for pork; these are well rubbed with dry salt, then placed in tanks, with dry salt, for at least ten days; the fluid parts of the meat, of course, ooze out and form a brine with the salt, a portion of the salt penetrating and hardening the meat; it is then placed in barrels, more salt being added at the top and bottom of each cask. From what we have observed above, this very rude procedure is evidently a wasteful and objectional process.

Mr. Whitelaw, of Glasgow, has introduced a process for utilizing the brine of cured meat. He remarks that fresh meat, after having been sprinkled with salt and left for a few days, is found swimming in brine. This expelled water was saturated with the soluble nutritive ingredients of the flesh; it was, in fact, a juice of flesh or soup, with all its valuable and nutritive properties. In large curing establishments, very considerable quantities of brine are produced and thrown away. To this material, Mr. Whitelaw has applied the process of dialysis, for the removal of the salt in the brine and the production of pure extract of meat at a cheap rate. He recommends the use of ox bladders with stop-cocks, hung on rods stretching across and into vats of water. The bladders were filled with filtered brine, and the water in the vats changed once a day or oftener; and he found that by the third or fourth day the saline matter was removed, and the liquid contained in the bladders was prime juice of flesh in a wholesome condition. This might afterwards be treated in different ways, according to circumstances; made into soup for immediate use, or evaporated at a low temperature, say 120°, for future use. He found that two gallons of brine yielded 1lb. of solid extract, equal to more than 30lbs. of fresh meat. He estimated that in Glasgow alone 60,000 gallons were annually thrown away. At the moderate calculation of one gallon being equal to 7lbs. of meat for the production of soup or extract, there was then a yearly waste of 187 tons of meat without bone, and which, at 6d. per pound, would give a money loss of £10,500 per annum. He has also used the same process for the reconversion of salt into fresh meat, by introducing into a proper dialysing bag the joint, and nearly filling it up with the brine; the fresh water extracts the salt from the meat through the brine, and the meat resumes some of the fluid extract it had formerly lost, to the extent, he says, of nearly one-third. Meat thus treated may be cooked in various ways that are not applicable to salt provisions.

Some notice of the charqui introduced into this country by the South American Beef Company and Mr. Madden will here be necessary; and, as we have been pretty well informed of the vast quantities of good wholesome meat in Brazil that only requires a market, the attention of all has been, for various reasons, turned to that quarter and to that subject. I shall endeavour, then, to be as brief in my remarks as the importance of the subject will permit.

The process for preparing the charqui is as follows:—The meat cut from the carcase is thoroughly salted with dry salt for 24 hours in stacks, on floors, which are channelled, for carrying away the brine into cisterns; it is afterwards thoroughly dried by exposure on rails in the open air. This forms the dry or original charqui; but a new plan has been used lately, viz., that of salting and pickling the meat with the bones, in pieces of about 12lb. weight, and packed in casks for transportation to this country.

South America afforded an admirable field for testing, on a most extensive scale, the process of salting introduced by Mr. Morgan, who stated in his paper, above referred to, that "an agent had been sent to Monte Video to practise the mode of preserving meat." As above stated, no large quantity has been received in this country.

An anonymous writer, I assume it to be Dr. Hassall, has recently, in a paper in the *Lancet*, spoken favourably of both forms of charqui, although he allows that in salting "it sustains a loss of a portion of its nutritive materials." An entertainment was prepared a short time ago, at which all the dishes, consisting of soups, Pemmican and other preparations were made from the South American beef; the results were variously reported. Dr. Hassall says, "the dishes were palatable and free from any perceptible taint, with the exception of the stewed beef, and such, in fact, as no hungry person would decline to partake of." Others I have heard complain of a certain mouldy, fusty flavour which even the excellent cookery of Mr. Warriner was incapable of concealing. In mentioning that gentleman's name, I must acknowledge the assistance he has rendered me in preparing this paper, and in providing the different specimens of preserved food exhibited on the table before you. I had proceeded far into my notes on charqui when the *Times* of the 7th current reported the seizure of about two cwt. of this dried kind of meat at Mr. Twelvetreese's, in Bishopsgate; this was condemned by the Lord Mayor, and burnt as unfit for human food. I have made inquiries as to the opinion of the poor who have used it in either form, and find there is an almost universal opinion against it, both from its appearance and uneasy smell in the raw state, but on the latter account more especially when it is being cooked. I am afraid that this South American beef, in its present forms and method of preparation, will never commend itself to the stomachs and appetites of our people. The decision of the Lord Mayor above mentioned appears to have been considered a heavy blow and great discouragement to those interested in the sale of the South American beef, for, in addition to the palliative advertisements that have appeared daily, a deputation of Liverpool merchants is about to remonstrate with the Lord Mayor concerning his decree for the destruction of the meat seized.

The analysis of the different samples of South American beef, compared with fresh and salted English beef, given by the abovementioned writer, is as follows:—

	LEAN ENGLISH.		Dried Charqui. Mr. Madden's.	Approximate correction for loss of water.	Dried Charqui. S. American Company.	Approximate correction for loss of water.	Rolled Charqui. S. American Company.	Approximate correction for loss of water.	Pickled Charqui. S. American Company.	Approximate correction for loss of water.
	Fresh Beef.	Salted Beef.								
Water	73.33	70.488	33.820	70.48	29.70	70.48	46.690	70.48	59.00	70.48
Fat	4.08	4.374	2.958	1.31	10.41	4.38	7.995	4.44	12.17	8.6
Nitrogenous matters, } Fibrin, Albumen, &c. }	20.76	18.170	40.954	18.86	39.69	16.72	27.500	15.17	15.40	10.97
Ash	1.20	0.165	20.456	9.12	18.55	7.81	16.860	9.31	11.87	8
Undetermined matters	0.63	0.803	1.812	.83	1.65	.61	.955	.60	2.06	1.46
	100.00	100.000	100.000	100.00	100.00	100.00	100.000	100.00	100.00	100.00

I have endeavoured to make an approximation of the analysis, in the dried or partially dried samples, to the standard of recently salted English meat, and the figures tally pretty nearly with those of the assumed standard. In all the specimens of charqui there is an excess of saline matters over and above what is necessary for curing the meat, but added, doubtless, for the sake of better guarding against taint or rancidity. This obtains to the greatest extent in the sample of rolled charqui, where the meat would, from its damp condition and exposure, require a greater amount of the preservative matters. A sample I inspected the other day, obtained from the Company, although freshly cut from the middle of a roll, and strongly impregnated with salts, insomuch that large portions of the crystals were sticking in the interstices of the meat, and the cut surfaces after a very short exposure became covered with powdery efflorescence of salt, had a very unpleasant smell resembling the odour of a small country chandler's store, and due, without doubt, to the partial de-composition of the fat of the meat, whether lying external to the muscles or in their substance, and the generation of some of the fatty acids which may be found to be deleterious. The dry charqui comes over to this country in bales. If it has been packed when not perfectly dry, or should it have become damp from any cause, the inner portions of charqui in the bale become heated and corrupt; or if no accident of this kind occurs the meat is attacked by mites. All the charqui brought over to this country has been cured not less than nine months. The fat is in excess of that in the English specimens in all the samples, except the dry charqui of Mr. Madden, and mostly so in the pickled beef; the sorters of the dry kinds at Liverpool cut off as much as possible of the fat, for which they obtain a better price than for the meat itself. As we might have inferred from what has been said of the effect salting has upon meat, viz., the abstraction of much of its water, and, dissolved in that water, of a great quantity of the soluble nutritious qualities of the flesh, so we see in the pickled beef that there is a manifest depreciation in the per centage of the nitrogenous principles; this depreciation in the nourishing proportions of the pickled beef requires some correction, as there exists a quantity of fat to the extent of double that of the English specimen; with this correction, however, the meat has undoubtedly lost a large proportion of its best constituents. In the case of the dried charqui of Mr. Madden, there appears to be an excess of the flesh-formers, but, again, due allowance must be made for the small quantity of fat. Taking this review of the South American beef, it must be evident that the meat *per se* is of good quality—very fit indeed for nourishing and invigorating our masses, but that some much more perfect system is required to preserve it before a ready market will be obtained for it here.

There appear, then, but three principal methods at present in use for preserving animal food from decay. The first, that of salting, certainly has some advantages, viz., that of being readily accomplished, and under almost any circumstances, although meat simply salted and dried can only be preserved for a limited time, the fat after a while becoming rancid, while the lean splits up from over-drying and offers an eligible habitat for insects, or if kept moist, mould and conservas may infest it. The acids and oily compounds generated by slow combustion of wood, carried out in the process of smoking salted meat, are greatly conducive to the preservation of this form of provision. When salt provision requires to be kept a long time, it is necessary to put it into casks with pickle. In this form it is most available for carriage, export, or import, but the same objection holds with regard to all salt meats, as has been shown above, that they are less nutritious and have lost some principles which are necessary to the animal economy, so that if the use of salted meats is persevered in without the due supply of fresh vegetable food very grave consequences result.

The second method, that of preserving cooked meats,

&c., is one that cannot be spoken too highly of; the process has borne the test of experience for years; the cases have been carried into every latitude; they have neither burst with the heat of the torrid zone, nor collapsed with the cold of the eternal snows; and whenever or wherever the contents have been required they have been available. This offers an admirable method of preserving, and at the same time cooking, food for import and for victualling. The food can be as varied in its form and combination as heart can desire, and the only drawback is the fear lest the food thus prepared should be over-cooked; this is evidently the greatest danger that can be conceived likely to occur, and one which undoubtedly does sometimes happen; yet an experienced and instructed cook ought to be able to carry out this process without so hardening the fibre of the meat as to make it injurious.

The third plan, viz., that of preserving raw meat by substituting an artificial and preservative atmosphere for that of common air, has, as I have before mentioned, many desirable qualities to recommend it. There is an opportunity of ascertaining the quality of the meat, poultry, &c.; the joint is to all intents and purposes as if just purchased at the butcher's shop; it contains all its ingredients and elements in a purely natural and unchanged condition, and in the state best adapted for nourishment; other advantages are the small cost of the process, and the speed with which it is accomplished; not the least being that the consumer is at liberty to cook his joint in any way most convenient or most desirable to himself. It is the only process of preserving by which we can obtain a roasted joint with all its appetising aroma, rapid gravy, and tempting brown exterior when served; it may be under the shadow of the pyramids, or on a Christmas day in the far north, to the delight and solace of some possible Arctic expedition. This process appears to be exceedingly applicable for the import of fresh raw provisions from countries where they can be obtained at small cost. It is available for putting up meat cut into joints suitable for the consumer, while it is not necessary to separate the meat from the bone, so that the shape and natural appearance of the joint are well preserved. The cases might be received in this country by the consignee, and the meat removed from them and dealt with as if just purchased at the carcass butchers, or, while in the cases, it might be transferred from town to town, as occasion might require; or, on the other hand, the meat would be in a ready and safe form for victualling armies or supplying ships. Indeed, whole carcasses might be packed singly or in numbers in tanks or in caissons furnished with tape; these might be treated in exactly the same manner as the tin cases for joints—instead of soldering on the cap it could be made air-tight, by means of binding screws, washers, &c. Suppose, for the sake of illustration, that a factory was established in any district where animal food might be found in great plenty, all the best portions of the animals, the joints, might be preserved and put up raw by the atmospheric process, while the parts not available for that procedure could be made into stews, curries, soups, ragouts, &c. These cases, both of raw and cooked food, might be then transferred hither and thither where most needed. Such a plan is about to be carried out by a company recently established, who will have a factory or factories abroad, and who are just starting a like business at home. They propose to purchase the cattle, pigs, poultry, fish, game, &c., at first hand, to slaughter and dress the cattle, and after preserving the finest joints by the raw-meat process, to put up the remainder by the cooking method. This will ensure all portions used not only to be fresh and free from taint, but to be obtained from healthy animals, and therefore most fit for human food, and conveying into the system the largest relative amount of nutrition.

It becomes a matter of necessity that this plan, or something like this, should be adopted, for we cannot shut our eyes to the growing wants of our population. The increased cost of animal food indicates a supply

not commensurate with the demand which may arise on the one hand from the wondrous increase of our own population, about 200,000 per annum, while there are but 60,000 who emigrate, one-third of these being English, thus leaving a yearly surplus of 140,000, without taking into consideration the immigration of foreigners; on the other hand, from the difficulty of supply of live stock or carcases from foreign countries, the cost of freight adding so much to the first cost of the animals if they have to be brought from greater distances than at present. Mr. R. Herbert, in a paper read before the British Association, at Bath, in September, 1864, remarks on the increased demand for meat due to "the rapid increase of the population of Great Britain during the last ten years, and the consequent increase in the consuming powers, added to the extraordinary progress of trade and commerce, the improved monetary position of the great mass of meat consumers, proving beyond doubt that the period has now arrived when strenuous efforts are absolutely necessary to meet a demand that must continue to have a most important bearing upon price. At the present time both beef and mutton are selling at full 14d. per pound above the rate current ten years ago. Prices are still tending upwards, and had it not been for a free importation nearly all kinds of meat would, long ere this, have been selling at enormous prices." The following table of the cost of meat per stone of 8lbs. will give the difference of prices at ten years' interval:—

	1853.			1863.			Average for		
	s. d.	s. d.		s. d.	s. d.		s. d.	s. d.	
Beef ..	2 6	to 5 0	...	3 4	to 5 2	...	3 9	...	4 3
Mutton	2 6	„ 5 4	...	3 6	„ 6 2	...	8 11	...	4 10

I believe the increase is more evidently shown by the prices of last year and the commencement of the present. The supply, too, of foreign animal food is becoming much larger year by year:—

	1853.	1863.	Increase.
Beasts imported ...	125,263	150,898	35,645
Sheep and lambs...	230,087	480,788	200,751

Calves and pigs also have been brought over in great and increasing numbers.

It is calculated that in London alone with, its 3,000,000 inhabitants, there are consumed—

Beasts	250,000
Sheep and lambs.....	1,500,000
*Calves	40,000
Pigs	400,000

It is a question of policy for the government of any country to see that its inhabitants are well supplied with wholesome food and in sufficient quantities. We are noted, as a nation, for the wonderful appetites we possess, and the appreciation we have for the best quality of food. Much might be done however towards husbanding the supplies we already have if a better and a more common-sense plan of cookery were adopted by all classes, but especially the poor. It is more than likely that our position among the nations is not a little due to this national taste for good, strong food and plenty of it. If, then, our energies of body and mind are to be kept going it is absolutely necessary that proper supplies of aliment should be forthcoming, and if this is not to be had at home we must go to other countries to seek for it. Good food is necessary, moreover, to good health. Unless our bodies are duly supplied with means to sustain the waste, they must become diseased and so decay. Witness the very marked difference of mortality amongst our troops in the Crimea and in Canada. In the former place, through our inexperience of war's requirements, or some other cause, proper attention was not paid to the victualling and hygienic necessities of the soldier; the dire consequence is that multitudes died of disease, while comparatively few succumbed in consequence of wounds; in the latter instance, that of the regiments sent to Canada

at the commencement of the present civil war in America, the troops were more tenderly cared for with regard to diet, clothing, quarters, warm food being ready for them after a march, extra rations of meat, fur jackets, flannel under clothing, &c. The consequence was that in a march during severe cold varying from 64° to 10° F. below the freezing point, Dr. Miles reported, "it is a remarkable and astounding fact that thousands of British troops, at the rate of 160 or more a day, have been during several weeks marched over a wide frozen desert of snow extending for more than 319 statute miles, yet during the whole of that journey, in all weathers, no single death had been induced thereby." He speaks also of the enormous appetites of the men, that they were eating morning, noon, and night. It has been calculated that a private soldier landed in India is worth to the state in money £100, that is to say it would cost so much to replace him in case of death; is it not, then, a false economy that withholds from that man anything that tends to his health and physical support? Moreover, if the soldier who protects what we possess is represented by such a sum, surely the civilian who produces wealth is of equal value. I trust the time is not far distant when our Government will no longer issue to the army and navy the accustomed supplies of salt provisions, but that with our present knowledge of processes for the ready supply of provisions in such condition as to be best adapted to support a sound mind in a healthy body, fresh food will be furnished to the well-being of our gallant defenders and the prosperity of the nation.

I may here observe that, from a comparison of the percentage of committals of criminals with the price of provisions, there appears to be a relative increase of crime when the food is high, and a decrease when food is cheap:—

Metropolitan Districts.	England and Wales.	
1856 3-2	19-4	} Dear food, foreign war.
1857 3-1	20-3	
1858 2-7	17-9	} Cheap food.
1859 2-9	16-7	
1860 2-8	16-0	} Good business.
1861 3-0	18-3	
1862 3-6	20-0	} Dear food and money.
1863 —	20-8	
		} Scarcity of cotton.
		} American war.

While in our densely-populated towns and districts we can scarcely supply sufficient cheap food for the bodily sustenance of our labouring population who chiefly require good animal food, while meat can only be obtained at an almost exclusive price to the poor man, and that meat frequently of but very indifferent quality, and while at the same time there exists in other regions of the earth a superabundance of animal food not only fit for sustenance but of excellent quality, it should be the duty of every philanthropist—to say nothing of mercantile and social interests—to make use of the abundance of one part of the earth for the supply of the necessities of another part, and thus act up to the precept of our great Exemplar, who required his followers to gather up the fragments, that nothing should be lost.

DISCUSSION.

Mr. WENTWORTH SCOTT remarked that by scarcely any known process for the preservation of food could all the nutritious qualities be retained, and this was the great end to be sought for. He had made a great number of experiments on this subject, but he had been able to bring with him only one specimen preserved by a process of his own. There were many processes by which both meat and vegetables might be preserved from decomposition, but these very generally produced a more or less disagreeable flavour, and he thought that remark applied to some extent to the foods prepared by Messrs. Jones and Trevithick. The specimen on the table, prepared by himself, consisted of a piece of veal which had not been

subjected to any process of cooking whatever. The air enclosed in the canister was atmospheric, but it was deprived of the elements of fungi and animal parasites by being exposed for a time to a temperature of 80° Fahr. It was then cooled and passed into the vessel containing the meat. After the meat had been "soaked" (so to speak) in that air for 24 hours, the air was removed from the case, and it was then re-charged with more "prepared" air, and a few drops of liquid ammonia were added to the contents of the vessel, which was then screwed down air-tight.

Dr. HINCHFIELD said he would not refer to the theory of this subject, but having on several occasions had the opportunity of testing different meats prepared by Mr. Jones's process, such as beef, mutton, ducks, and fowls, he could bear his testimony to their perfect freedom from the least taint from the gases employed in the process of preservation, and he considered the meats were as good as if they had been perfectly fresh.

Mr. WARREN said, as a practical cook, he might be able to throw a little light on a matter which seemed so generally interesting as to have brought together such a large audience on this occasion. With reference to the preserved viands, of which those present would afterwards be invited to partake, he had no doubt they would be found excellent. It was now nearly 20 years since he received the Isis gold medal of this Society for the introduction of the concentrated essence of meat, a distinction which he should feel proud of to the latest day of his life. His object in rising was more particularly to call attention to the process of Mr. Jones, by which raw meat had been preserved in a good sound condition for more than three years, and the process, as witnessed by himself and Dr. Lothely, the officer of health for the City, was extremely simple, and the only wonder was that it had been so long overlooked. Raw meat could be obtained in Russia, in South America, and other parts of the world, at a half-penny per pound, the only additional cost being the preservation and the transport to this country, besides the profit to the dealers, which in London was much higher than in any other place he knew of. With regard to the charqui he was not in a condition to say very much about it; at the same time, if it could be brought to this country in a good condition, and in perhaps a somewhat more tempting form, it would prove a great boon. He would suggest that they should feed convicts on charqui, and leave the English beef and mutton for the honest labouring population. He felt convinced that the price of meat in this country might be greatly reduced from what it now was, if men of science would only give the attention to the subject which its great importance demanded. It was the duty of every one to endeavour to lower the price of the staple articles of food, so as to bring them within reach of the great masses of the population. He did not decry charqui because of its untempting appearance; but the great question was whether it contained the necessary nutritive qualities which all food should possess to make it really valuable. They would have an opportunity of tasting soup made from both charqui and English beef, and he would leave them to decide which they liked best.

Mr. FRIZZ, as the representative of the South American interest in Liverpool, said he had listened to the paper with great interest, and he thought the various processes brought under their notice had been very fairly and truthfully described, each standing on its own merits. He had probably had more to do with the imported South American beef than any other person, having received large consignments, all of which had been consumed. The other description of preserved meat with which he had a good deal to do was that prepared by Mr. Morgan's process of salting, and he had that day partaken of a dish of stewed mutton from Australia, preserved by that process, which for flavour and good condition was all that could be desired. He believed they were on the eve of a different state of things with regard to animal food in this country, and if only a fair trial was given to the various

foods brought before them this evening, and if popular prejudices was not allowed to prevail, they would have the means of largely increasing the supply of animal food, which was allowed by all to be greatly needed, and would thus add to the welfare and comfort, as well as to the wealth of the country.

Mr. KEMMEL remarked that the great object was to ascertain some means by which animal food might be obtained at a much cheaper rate than at present. The labouring populations of France and Germany were taught to economise food to a far greater extent than the poor of this country, and, generally speaking, he believed the people were more economically, and at the same time more nutritiously, fed in those countries than in England. The greatly enhanced price of animal food in this country at the present time was a matter of the most serious importance, and unless some effectual means were taken to counteract this, the price would go on increasing. The importance of this question had been increased by the disastrous civil war in America, by reason of which large supplies of animal food had ceased to find their way across the Atlantic. If means could be devised by which good animal food could be brought into this country for general consumption, it would be a most desirable thing, and would supply a great want of the present day, and those who succeeded in effecting that object must be regarded as public benefactors.

Mr. WINTER wished to know whether the preservative processes introduced to their notice this evening were to be regarded as novelties? He had given attention to this subject for some years; and seven years ago he preserved meats and fruits in their natural state by machinery, which he should be happy at any time to exhibit to them interested in the subject.

Mr. W. V. VENABLE expressed the great delight which he and other sojourners in distant countries had experienced from the means which were afforded them through the various preservative processes in use, of regaling themselves with home delicacies. This, he said, was particularly the case with regard to salmon, which was now procurable almost everywhere.

Dr. EDWARD SMITH, F.R.S., said he would refer more particularly to one kind of preserved meat, charqui, for it appeared to him very desirable that they should, if possible, come to some conclusion as to the real value of that description of food. Some three years ago there was reason to hope that the vast stores of animal food in South America would be made available for this country, but he was sorry to see the result had not equalled the expectations in that respect. One important element in the case had been omitted both from the paper and the discussion, that was the price at which that food could be sold in this country. It was originally introduced with the catching announcement, "Beef at 3d. per lb." whereas, when they went to buy it retail, they found it was 4d. per lb., which made the greatest possible difference. That description of meat was never intended to come into competition with the sirloin of beef and the leg of mutton, which were the food of the rich; but if there was any use in its introduction at all it was in competition with the inferior parts, which for the most part fell to the lot of the poorer classes as being within their means. The poor man was now able to buy on a Saturday night his piece of brisket of beef at 5d. to 5½d. per lb., or heart at 4d., and liver at 2d. to 2½d. per lb. Without going into the question whether these were the best representatives of animal food they were certainly the most available for the poor population, and he thus conceived that the South American beef came into competition with them alone. It seemed to him a great mistake to allow that kind of meat to be sold so high as 4d. per lb. If the meat could be obtained almost without cost in the countries where it was produced, and if the cost of curing—especially by the process of Mr. Morgan—was so small, to which only had to be added the expense of transport, he was quite

me it could be sold in this country at 2d. per lb., and have a fair margin of profit to the dealer. If that were the complexion of the whole subject would be changed. Now, with reference to charqui itself, as now imported, they had heard very truly that the salting diminished its nutritive value, and the specimens before them were very highly salted; even if they soaked this meat for 48 hours, frequently changing the water, there was still salt remaining. He had treated it in that way, and then simmered it gently for 12 hours, and it then remained almost as hard and dry as it was at first. The hardness and saltiness were both bad qualities, the former showing the absence of the nutritious elements of meat and the excessive amount of fibre; and the latter exercising a prejudicial effect upon the human frame, inasmuch as an excess of saline water was injurious to the nutrition of the body. Then came the question whether the amount of nutrition that was left in the meat, in the shape of nitrogen, existed in a digestible form. Here they had a material so extremely hard that with no amount of soaking and careful cooking could they reduce it to a condition which would bear comparison with fresh meat. They might be sure a large portion of the fibre passed away from the system undigested: therefore, instead of this meat being more nutritious than fresh meat, as had been in some cases erroneously asserted, it was very much less so. This subject bore indirectly on the introduction of food into prisons and workhouses, but it would be no economy to introduce a description of food that would not supply an equal amount of nutriment for an equal amount of money to that now spent for fresh meat. It would be the dearest food that could be used: food which was hard, salt, and indigestible, at 2d. per lb., was, in fact, a dear food. This description of food was said to have been imported principally with a view of benefiting the poorer classes, but it must be remembered that no benefit would accrue if there was a difficulty in cooking it. In many districts the fuel of the poor consisted merely of faggots, brambles, and hedge-gatherings, and therefore the lengthy cooking which this description of meat required was all but impossible to them. Then, again, came the questionable flavour of this South American beef as at present served. Of all classes of the community the poor, perhaps, the most dainty. In this case they had a hard and indigestible. The flavour was removed by the excessive salting process, and cook it as they would there was an exceedingly small amount of taste in it. To his mind it was impossible that this article of food in its present form could ever become acceptable amongst the people. The higher classes did not want it, and the lower classes would not eat it. What they all desired was to see a large amount of wholesome and palatable flesh food introduced into the country at prices which would compete with the lower-priced joints of fresh meat.

Mr. G. F. WILSON, F.R.S., wished to state, after what had fallen from Dr. Smith, that he knew an instance in which South American beef was tried in a workman's slay at Birkenhead. It was bought at something less than three-pence per lb., and when made into soup was considered to be good.

Mr. MADDEN and his name having been mentioned in the paper in connection with the subject of South American beef, he wished to state that he had done his best to make it as popular as possible. Alluding to the public entertainment recently given by him at the London Tavern, consisting of various preparations of charqui, Mr. Madden stated that it was partaken of by 2,000 persons, who went "quite satisfied," and the cooking occupied very more than twelve hours. With regard to the price of meat, he was prepared to supply portions of 7 lbs. per lb., and if anyone wished for a large supply he furnished him with 100 tons at 2d. per lb. With regard to Mr. Jones's process, he would say he never partook of better tasting food, and it ate as fresh as if the meat had only just been obtained from the market.

Admiral Sir E. BELCHER said, having been accustomed to the use of preserved and salted meats for over half a century, he might be supposed to know something of their value amongst seamen. In the Arctic service the men preferred salt meat to the fresh meat preserved in tins; of the latter the beef steaks only were in favour, the mutton and soups being entirely eschewed. Charqui, in his opinion, could not, by any possible means, be made a food for the army or navy. It produced thirst, it required a great deal of fuel to cook it, and was not so nutritious as other foods. He had had charqui privately prepared for him in South America, and it was esteemed at the captain's table, but the men would not touch it. For the officers it was an agreeable change of diet from the salt beef known as "mahogany" (which was infinitely more difficult to "work up" than charqui), to have the preserved meats which were now taken out in all ships, and available in all climates. The consumption of animal food by men in the navy and soldiers abroad was much less than the average at home; and in the Arctic regions, travelling over hundreds of miles with the drag rope, with an allowance of three-quarters of a pound of meat per man per day, and the usual rations of biscuit, the men were in a more plump condition than when they started. Amongst the earlier forms of preserved meat was the patent of Mr. Payne, and he had used provisions prepared by that process with great satisfaction on the north-west coast of America. In the early part of the present century, the admiral in command on the West India station introduced a method of preserving meat in hot climates by simply rubbing it with sugar, and then allowing it to drain for a short time, afterwards packing it in dry salt in a cask. He induced the government to try that plan, and the whole of the meat used in the Arctic expedition in 1852 was cured in that way, and remained good throughout. In addition to that he took as a reserve several casks of beef prepared by Mr. Hogarth in February 1852, and in December of the same year he had roast beef as fresh as if it had just come from the butcher's shop. In the August following he had rump steaks from the same beef, and in the December following roast beef again. A preparation of meats with pyroligneous acid had been successfully adopted by Sir Thos. Cookhane, the meat being used many months afterwards in tropical climates, and found to be perfectly good. Having referred to the meat biscuit rations served to the soldiers in America as a nutritious and very portable form of food when on march, as also to the truly American rapidity with which the carcass of a bullock was compounded with flour and converted into that form of food, Sir Edward Belcher, reverting to the subject of charqui, remarked that when he was on the western coasts of America, he found that really good charqui never required more than twelve hours' soaking; being put into cold water at night it was fit to be cooked the next morning. Placing the meat in warm water did not soften it, and the best mode of softening it was by repeated changes of cold water.

Dr. BACHHOFFNER remarked that he was conversant with most of the processes adopted for the preservation of food; and with respect to Payne's process, alluded to by the last speaker, notwithstanding all the care and expense bestowed upon it, it was a decided failure in hot climates in consequence of the difficulty, under such circumstances, of getting the salt to penetrate into the meat before decomposition set in. Rapid decomposition in tropical climates was the great obstacle to the salting process, but in colder climates this did not exist. It was not, however, in temperatures like that of England that the salting process was greatly required; at the present time the meat was eaten almost faster than they could get it. He remembered, about twenty-two years ago, a process similar to that described in the paper was proposed, in which the antiseptic properties of nitrogen were made available, though in a different mode.

The meat was enclosed in an air-tight vessel, and the gradual absorption of the oxygen was effected by the previous deposition of a small piece of phosphorus at the top of the vessel, and this was not found to interfere with the quality of the meat. They had not been informed as to the cost of producing the nitrogen for this purpose: nothing had as yet been said as to the means employed for obtaining it, or the cost of it when obtained. That was not a minor consideration, because they were told that a double application of nitrogen was required, which involved a large consumption of that gas. If that process could be adopted in warm climates it would be much preferable to the use of saline matters. On the first introduction of preserved meats into France, in 1811, the Emperor Napoleon rewarded the inventor with a liberal premium or pension. For his own part he must say he infinitely preferred the meats preserved in tins to the charqui recently introduced, and he should particularly rejoice if, by means of curative processes, salmon could be obtained at 1s. per lb., instead of having to pay the present high price of 3s. 6d. per lb.

Mr. DAVIS called attention to two pieces of raw beef on the table which he said had been cured by Mr. Morgan's process in Adelaide, six months ago, at a time when the temperature was 85°, and had since been brought home in the hold of a wool ship, which every one knew was particularly hot. That process of injection, immediately after the animal was slaughtered, he apprehended might be safely adopted in the hottest climates.

Mr. JONES stated, in reply to the inquiry of Dr. Bachhoffner, that the cost of nitrogen gas did not exceed the eighth of a penny per lb. of meat. On a large scale it would be even less than that. In the first instance, he formed the binoxide of nitrogen from nitric acid and iron plates, and then produced the nitrogen gas by further decomposition.

The CHAIRMAN said he was sure the meeting would cordially join with him in according their best thanks to Mr. Steet for the very admirable manner in which he had introduced a subject of great importance in the present day, and which had elicited so interesting and practical a discussion. It was a subject which was occupying a large amount of public attention. The discussion had already lasted so long that at that late hour he would not trouble them even with the few observations he had intended to offer, but he would call upon them to give their thanks to Mr. Steet for his very valuable and interesting paper.

The vote of thanks was then passed.

Various specimens of preserved food were kindly contributed by the following gentlemen, to whom the thanks of the Society are due:—Messrs. M'Duncan, of Jersey—Cods, tongues, salmon, lobster, &c., in tin cases; Messrs. Hogarth—Roast and boiled meats, in tins; Messrs. E. Collier and Co.—Salted and dried fish, the "Bonets" and "snapper" from Spain, as well as preserved potatoes and compressed vegetables from Holland; Mr. Jones—Specimens of fresh meat, poultry, vegetables, and fruit, in glass cases, preserved by his process; Mr. Davis—Meat preserved in South Australia by Mr. Morgan's process.

Mr. W. Symons exhibited an ale-preserver, of which a description will be found at page 321.

At the conclusion of the meeting those present adjourned to the Society's library and partook of various dishes, prepared under the kind superintendence of Mr. Warriner, from the different sorts of preserved food above referred to.

Proceedings of Institutions.

LEEDS PHILOSOPHICAL AND LITERARY SOCIETY.—The report of the Council at the close of the forty-fourth session says that both as regards its financial and numerical position, the society is in a prosperous state. Seventy-

six members and subscribers have been elected during the past session. In consequence, however, of several unusually heavy but unavoidable items of expenditure, trenching upon the ordinary funds, having occurred, the balance in favour of the society is not so large as at the close of the previous year. With regard to the expense of the alteration of the building, the amount received has been £11,128 15s. 8d., while the cost has been £11,515 13s. 11d., so that a deficiency of £386 18s. 3d. still remains against the society. The Council record the great loss which the society has sustained in the death of Mr. William Gott, who, from the first formation of the society, took the most lively interest in its advancement, and especially in the improvement of the museum, and was always ready with his purse to assist in the purchase of desirable objects. By the removal from Leeds of Mr. O'Callaghan the society lost the services of an active and valuable officer. During the last seven years Mr. O'Callaghan has been one of the honorary secretaries, and has devoted his entire time and energies for the benefit of the society. The papers read at the general meetings have been of a varied and highly interesting character. Among them may be mentioned one "On the Physical Constitution of the Sun," by Edward William Brayley, Esq., F.R.S., &c.; one "On Roger Bacon, his Life and Works," by Thomas Marshall, Esq., M.A.; one "On the Geology of the North of England," by Professor Robert Harkness, F.R.S., F.G.S., &c.; one "On the Sources of the Nile," by Dr. Charles T. Beke; one "On the Early Domestication of Animals," by Francis Galton, Esq., F.R.S., &c.; one "On the Unity of the Human Species," by George Rolleston, Esq., M.D., F.R.S., Professor of Anatomy in the University of Oxford; and one "On the history of Leeds before the Norman Conquest," by Thomas Wright, Esq. During the Christmas vacation two juvenile lectures "On the history and progress of the Electric Telegraph," were gratuitously delivered by Mr. Dodwell, of Manchester, with numerous illustrative experiments; and a course of four lectures was also delivered by Professor D. T. Ansted, on the following subjects:—"The influence of Water in forming Rocks;" "The influence of Water in modifying rocks;" "Granite, its origin and history;" "On the early races of Men, and their Contemporaries." The annual conversations was attended by a very large number of the members and friends of the Society, on which occasion a great variety of objects of art and historical interest were exhibited. The receipts from this source have amounted to £149 10s. 5d. The museum continues to receive many valuable accessions by donations; and as an educational collection for illustrating the higher groups in zoology, is probably second to no provincial museum in the kingdom. Mr. Salt, of Methley-park, having most liberally offered to kill one of his finest specimens of alpacas, for the society's museum, the Council, while accepting the valuable present, considered that so good an opportunity for enabling the members to partake of the flesh of this only partially acclimatized animal should not be lost, accordingly a dinner was prepared at the Queen's Hotel, where about 60 gentlemen assembled, and the council had the pleasure of receiving Mr. Salt as their guest. The department of archaeology has been more than ordinarily enriched by the acquisition of specimens of local and general importance. From the Rev. John Gott has been received a valuable series of Greek marbles, consisting of altars, mural tablets, and inscribed stones, collected in Athens and other Greek cities by the late Benjamin Gott, jun., Esq. The additions to the library have been of an important character. Since the last annual meeting a MS. catalogue has been prepared, by which it will be seen that it now contains about 2,000 volumes. Another addition has been made to the picture gallery, which was commenced last year, consisting of a fine oil painting by Ruydael, presented by Mr. Arthur Lupton. The collection of British plants, which has

has annually increasing for a number of years, and based upon the Linnæan system, has been considerably advanced in value and usefulness through the kindness of the Rev. C. H. Middleton, who has devoted much time and labour to the complete examination and entire re-arrangement of the specimens upon the natural system. In the report for last session, the importance of establishing an Industrial Museum in connection with the Society's operations, was brought before the members, and a sub-committee was appointed to carry out the preliminary arrangements, and their labours have been so far successful as to promise a speedy opening of the room appropriated for the purpose. Various presents have been made to this museum, such as samples of the different resins from which oils for commercial purposes are expressed, a case of colonial wools, various kinds of cochineal, specimens illustrating kelp and its products, and various kinds of sheet gelatine. Many specimens have been furnished from the South Kensington Museum, as well as between 300 and 400 glass jars, for containing specimens, also a complete set of printed tablets for describing a food collection. The committee have brought the objects and claims of the museum under the notice of Dr. J. Forbes Watson, of the India Museum, and they are much gratified at finding that this gentleman is anxious to extend the influence of the Department over which he presides by enlisting the services of industrial museums in the provinces in bringing before the manufacturing communities materials capable of industrial uses. Applications have been made to about 60 firms for specimens of the materials employed by them in various arts, and hardly a refusal has been received. The cash account, from May 6, 1863, to June 30, 1864, shows that the receipts have been £1,061 1s. 1½d., and that there is a considerable balance in hand.

NEWCASTLE-UPON-TYNE CHURCH OF ENGLAND INSTITUTE.—The eleventh annual report speaks of quiet prosperity and steady progress. The number of members has increased from 376 to 400 during the past year. One hundred and eighty-two volumes have been added to the library. The reading-room is well attended, and the circulation of books continues to be very large. The Council specially urge on the members the importance of using every effort to enlarge the sphere of its usefulness. The Soirée held on Whit-Tuesday, under the presidency of the Mayor of Newcastle, Thomas Hedley, Esq., was, as it always is, successful in a pecuniary point of view. The lectures were particularly interesting, the room having often been inconveniently crowded. Among the lectures given were one by Rev. J. J. Taylor, M.A., "A Ramble among the Ruins of Pompeii;" one by T. Austin, Esq., on "Monastic Life;" one by Rev. W. A. Scott, M.A., Incumbent of Seaham, on "The Catacombs of Rome;" one by Mr. G. J. Baguley, on "Painted Glass," illustrated by cartoons of ancient and modern examples; one by W. D. Crowdon, Esq., on "Iona—its History and Associations;" one by Archdeacon Priest, on "Palestine;" and one by the Rev. Canon Dykes, M.A., on "The History of English Church Music," illustrated by a choir. The classes are:—French, Singing, Photography. The first is decidedly successful; the second, hardly so flourishing as might be expected; the third is conducted gratuitously, but is not very well attended. The free admission of elder scholars from Sunday-schools to the benefit of the Institute is still considered to be of great advantage to them. The librarian's salary has been increased, on account of the additional labour which the new arrangements have caused. The treasurer's account shows that the expenditure has been £314 8s. 1d., and that there is a balance due to the treasurer of £7 15s. 5d.

DUBLIN INTERNATIONAL EXHIBITION.

The colonial arrangements are making great progress, and accounts continue to arrive of very fine collections being on the way.

In Victoria a board has been formed, consisting of the following gentlemen:—Sir Redmond Barry, Chairman; Professor Mneller, Professor McCoy; A. R. C. Selwyn, C. E. Bright, W. W. Wardell, and R. Brough Smyth, Esqs.; Mr. J. G. Knight being Secretary. An attractive series of products had been secured for transmission to Dublin. Among the contributions will be a choice collection of fleeces, selected from the stock exhibited at the recent great intercolonial show; samples of the new crop of cereals, contributed by the Board of Agriculture, and specimens of the manufactures of most of the claimants of Government premiums for "novel industries." Contributions of minerals, timber, fruit, tobacco, silk, flax, &c., are also promised. Application has been received by the executive committee for 1,500 superficial feet of floor space, to be reserved, for the productions of this colony. The goods were to be shipped by the Great Britain, which was to leave Melbourne on the 10th March. From New South Wales, New Zealand, Tasmania, and South Australia, collections are also expected.

In Mauritius a Committee has been appointed for the purpose of promoting in the island the design and intention of the Exhibition. The same sum has been voted by the Legislative Council (£250), upon the recommendation of the Governor, Sir H. Barkley, as on the occasion of the two International Exhibitions held in London, and on that of the Exposition held in Paris, to be applied as may be required for the promotion of the object in view. A fine collection of sugars, fibres, vanilla, tobacco, matting, and various other products, arrived overland by the last mail steamer at Southampton.

Jamaica, Dominica, Trinidad, and other West India colonies will be represented. Natal sends a small but interesting collection of produce and native curiosities and other articles.

There will be an interesting collection of products from the Hawaiian (or Sandwich) Islands; and among the other distinguished personages who will visit the Exhibition will be Queen Emma, her Hawaiian Majesty.

RURAL COTTAGES.

By G. H. WALKER, Esq.

As the attention of the Society of Arts, and of many persons throughout the country, is now most usefully turned to the means available for improving the dwellings of the labouring classes, I am desirous of adding my mite to the common stock of information on the subject.

I find a general impression prevailing—an impression confirmed by, if not derived from, the various designs and estimates of costs that have been from time to time published—that good durable rural cottages, with two or three bedrooms, must necessarily cost something like £150 a-piece, a sum for which labourers cannot pay adequate interest in the shape of rent.

I think this impression is erroneous, and that it seriously obstructs the good work which it is now one of the objects of the Society of Arts to promote; and I think I shall be able to show that such cottages may be constructed, in a thoroughly satisfactory manner, with all usual and necessary appurtenances, for £80 or £85.

Ten years ago I built, near Rugby, for £70 a-piece, the four cottages in one block, of which plans and sections are given above. They are built of brick, slate, blue lias lime, and good foreign timber, and well drained and spouted; with a layer of slate in the walls to prevent damp rising above the foundations. They have each a wash-house, pigsty, &c., and the block is supplied with a pump and well, and the total cost of the four dwellings—including everything but the value of the land—was £280, or just £70 a-piece. As I employed no architect, and had the cottages built by a working mason of sufficient ability, on contract, there was no addition to the actual cost of con-

struction. However, I am authorised by a builder of the highest respectability, Mr. John Bromwich, of Rugby, to say that he is prepared to build similar cottages, under similar (that is, I believe, average) circumstances, by the dozen, at £80 a-piece. There was no undue favour given to these cottages; though the bricks, lime, and sand came from the estate, they were charged the full market price, and had to be hauled a mile over bad parish roads.

The economy of these cottages consists in their extreme simplicity; in there being four together, back to back and side by side, with one stack of chimneys for the eight flues, one for each principal room of each cottage.

I am aware that there is a general idea that cottages built back to back are not healthy. In large towns, and under certain circumstance, this may be so, but in the country, with two sides of the cottage open to

FIG. 1.—GROUND PLAN.

FIG. 4.—LONGITUDINAL AND CROSS SECTIONS.

the air, I am convinced that it is needless to incur considerable additional expense by rejecting this arrangement. These cottages have never been objected to by tenants or visitors, and an inspection of them would show that a cottage thus built may be as sweet, wholesome, and comfortable as one that has a thorough draft from back to front—probably much more so. We do not know how much discomfort and sickness are produced in small cottages by that "thorough draft" when the doors are ill-fitting or frequently open. The fireplace in the angle of the living room, and thus radiating into all parts of the apartment, is found very conducive to comfort and economy of space.

It will be seen, by an inspection of the plan, that by a trifling expenditure—say £5—in a porch, with oblique doorways into the "living room" and the room adjoining, (with some change in the position of the staircase) the latter may be converted into a third bedroom.

These cottages let readily at 2s. a week, a sum that agricultural labourers getting 12s. or 13s. can afford to pay; and that rent yields an interest on the £70 of about $\frac{7}{8}$ per cent., subject to deductions which certainly leave a good 6 per cent. I may mention that these have been very favourite cottages, and from the first not one has been left by a tenant willingly. They have hitherto, after ten years' occupation, hardly cost anything for repairs, nor do I believe that they will do so for 50 years to come if they receive ordinary care and attention at the hands of the occupants.

I have mentioned that the value of the land is not included in the cost; but as only about one-hundredth part of an acre is covered by each cottage (or a tenth if the garden be included) it is hardly necessary to take it into account. Land in rural districts may be laid at its agricultural value, say £2 an acre, so that the cottage would occupy land worth 6d., and the cottage and garden land worth 4s. per annum. As a general rule land used for cottage building need not be debited to their account by landowners, for the additional value given by them to the adjoining ground for gardening purposes more than compensates for the land occupied by the buildings themselves.

Of course the above design and calculations only apply to rural districts, but it is there that the greatest difficulties are generally felt, because of the very low wages of the rural peasantry. In towns, where land is much dearer, and building is so to some extent, the earnings of the working classes are larger to a much greater degree; and when six or seven shillings a week are readily paid for the arrowest accommodation there should be no difficulty in providing plenty of dwellings at amply remunerative rates. Of course the arrangement and style of building must be totally different from those of rural cottages, but while in many respects they must be more expensive in some important particulars, they may be more economically constructed. Upon the whole the balance of advantage

financially must be with the town; it must be less difficult to make the income cover the expense there than in the country.

ALE PRESERVER.

The following is a description of an instrument invented by Mr. W. Symons, F.C.S.:—Ale and beer when on draught is rendered flat and sour by means of the air which must enter the cask as the liquor is drawn off, and this will be the case whatever contrivance (as patent vent pegs, syphon taps, &c.) are used. The place of the liquid must be supplied, or the tap will not run, and the atmosphere must always have an injurious effect on the quality of the ale or other liquor. In this apparatus, while the ale can be drawn with the greatest freedom, the air is perfectly excluded, and carbonic acid gas supplied in its place. As there is thus no free oxygen allowed to enter the cask, no acidifying from this cause can take place, and the bad effects of an ill-ventilated cellar are also prevented. It is well known that the superior quality of bottled ale and stout depends on the carbonic acid gas said to be contained in it, which is set at liberty when the cork is removed, and thus the effervescence is produced. By supplying carbonic acid instead of air to the cask a portion of it is dissolved in the ale, which imparts to it some degree of the briskness of bottled ale, in addition to keeping it from turning sour. To use the apparatus for a 9 gallon cask, put 1lb. of common washing soda in small lumps into the inside glass S; in the

stone jar, J, put sufficient water to reach to the small part of this glass, as shown by the dotted lines, which should have been a little higher. Into this water put about 5 oz. by measure, or 8 oz. by weight, of sulphuric acid. Screw the brass vent peg, V, into any convenient part of the top of the cask; place the stone jar, J, on a shelf at a convenient distance from the cask; put the large glass, G, over

the one containing the soda, both of the glasses being in the acid and water; attach the apparatus to the vent peg, V, by the India rubber tube, T, and it will require no more alteration until the cask is empty, unless the weather be very warm and dry, when a little water may be required to allow for evaporation. When ale is drawn from the tap the acid and water in the jar J will rise into the glass, S, and on reaching the soda effervescence will take place, and as sufficient carbonic acid is disengaged, the water will sink to its usual level, thus removing the acid from the soda until more ale is drawn. If the water does not rise in the glass, S, when ale is drawn, it shows the cask is not properly stopped at the bung or elsewhere, thus giving an indication the cask is not as it should be. As sulphuric acid can be easily procured in quantities of 6lbs. or so at about 3d. per lb., the working expense will be less than 8d. for a cask of nine gallons, and persons who have gardens may utilize the waste product by adding it to the manure heap.

Fine Arts.

ENCOURAGEMENT OF ART IN FRANCE.—The annual exposé of the situation of the empire contains a long list of works of art purchased, and of public monuments created, restored, or beautified at the cost of the Government. In painting, the most important commissions executed or commenced during the past year were:—The decoration of the Grand Court of the Invalides, the walls and vaults of which are being covered with subjects drawn from the most memorable periods of French history; of the Chapel of the Senate; of a portion of the Cathedral of Agen, and of many chapels in Paris. The Galleries of Versailles and the Luxembourg have received a number of historical portraits and other works. The Polytechnic School and the Hotel of the Minister of War have been presented with portraits of celebrated savans educated at the former establishment, and of military celebrities. The decorations now being executed at the Museum of Amiens have been aided by a grant from the public purse, and that and other provincial galleries, prefectures, sub-prefectures, and mairies have had a large number of original pictures and copies presented to them. The commissions to sculptors and purchase of sculpture have been numerous. Amongst others may be mentioned statues of the Empress Josephine, for Versailles; of Vaucanson, for the Conservatoire des Arts et Metiers; of Baron Desgenettes for the Imperial Academy of Medicine; a number of historical figures for the niches of the Old Louvre, and a number of busts of celebrated men for the Louvre, Versailles, and the libraries of the Institut and of the Conservatoire Imperial de Musique. A bust in marble of Jacquart has been presented to the town of Roubaix; one of Bayard to Grenoble; and a portrait of a prelate, native of the town, to Tours. A statue of Gaston Phœbus was presented to the town of Pau; and the State has subscribed towards the following monuments:—That of Marshal Davoust, at Auxerre; of Mezeray, at Argentan; of Jean de Rotrou, at Dreux; of General Pajol, at Besançon; of Dom Calmet, at Commercy; and several others. A very important work achieved during the year was the reproduction, by the galvano-plastic process, of the bas-reliefs of the Trajan column, now exhibited in the New Louvre, and which have been noticed before in the *Journal*. Another was the restoration of the statue of Napoleon, after the original design, on the Colonne de la Grande Armée in the Place Vendôme. A statue of the present Emperor is now in hand, destined to record the annexation of Savoy and Nice to France.

INTERNATIONAL FINE ART EXHIBITION AT AMSTERDAM.—In addition to the exhibition to be held in the New Crystal Palace at Amsterdam, another for the works of art of all nations is announced to open on the 4th of Sep-

tember next, and to remain so until the 9th of October, or later, if the committee see fit. The managers of the undertaking pay the cost of conveyance by the ordinary luggage trains, but the exhibitors have to bear the expense of the return of their works. The last day for their reception is the 4th of August. Six gold medals, of the value of one hundred florins each, are mentioned as prizes, but no others.

Manufactures.

STEAM ROLLER.—A huge machine for crushing and consolidating the broken stone on the macadamised roads of Paris, has lately been tried in one of the great new boulevards, and in other places, and it is reported with a satisfactory result. The new steam roller consists, in the first place, of two very large cast-iron rollers, which are coupled together by means of two endless chains acting on ratchet-wheels attached to one side of each of the rollers, the boiler being placed over one of the rollers and the cylinders nearly in the centre between the two. The axles of the two rollers are so arranged that they may be thrown out of parallelism, and thus enable the machine to turn round with a circle of about five-and-forty feet diameter. The whole machine weighs seventeen tons, which is more than double the weight of the largest roller heretofore employed, and it is said that the economy amounts to 60 per cent. as compared with the old method.

SWISS WATCHMAKERS.—Mr. John Bennett, in a lecture entitled "A month among the Swiss watchmakers," draws attention to the fact that from England we are sending a million pounds sterling a year to the people of Switzerland for watches for home consumption. He had determined to learn what were the causes of this superiority on the part of our Swiss rivals. He had found that they had a better system. They had a common standard of measurement decimalised; they had far better tools; and they knew the value of female labour. But at the root of all their superiority lay their admirable system of universal education. To this most especially must be attributed their extraordinary success. The Swiss eighty years ago made but 2,000 watches; fifty years ago they made 8,000; but ten years since one million and a-half of watches were made in the district of Neuchâtel alone. Their leading men, years ago, were wise enough to perceive that the only way to produce perfect watches was first to perfect the workmen. They declared that ignorance was a pest in any community, and even a criminal offence; they established by law the means of education in every village; they declared that education should be gratuitous, but also compulsory and universal; and from time to time since those regulations were first put into force they have never failed to apply all the powers of later experience to the improvement of their educational system. Hence the superiority in the broad silks of Zurich—in the lovely ribbons of Basle—in the exquisitely plaited straw of Lucerne—in the articles of personal decoration of Geneva—in the rifles of Moudon—and in the watchwork of the Jura mountains. The cultivated intelligence and artistic taste of the people of this busy hive of industry produce watches in tens of thousands, of a character, for external beauty of form and decoration, for precision of mechanical construction, and for cheapness of cost, which has forced their sale in every quarter of the globe. Mr. Bennett gave an instance of the importance the Swiss attach to the most improved system that can be applied to the purpose of popular instruction. About ten years ago the village of La Chaux des Fondes, occupied almost entirely with watchmakers, and situate at the highest summit of the Jura mountains, was dissatisfied with its educational institutions. They had secondary schools, primary school normal schools, for the preparation of teachers, and during the winter, when perhaps the snow was lying six feet deep

on the ground, they had half-a-dozen schools spread round the suburbs, so that half the masters went to the scholars when the scholars, from the state of the weather, could not come to the masters; and yet the system was not considered sufficiently complete to ensure the future success of the rising generation of workmen. The watchmakers met. They got plans for a new college to accommodate 1,000 scholars; they obtained a grant of £7,000 from the Federal council; they subscribed £5,000 amongst themselves; they built a college at the cost of £20,000, and raised the balance of £8,000 on the security of their local taxes. Hence the superiority of this most remarkable people, hence their welfare and prosperity, and hence, too (said Mr. Bennett), if we did but know it, a striking example which we may wisely take as a model for the improvement of our own social, intellectual, and political condition.

MICAGRAPHIE.—This is the name given to a new process of producing ornamental effects on sheets of mica. The facility with which this mineral cleaves into thin sheets, and its transparency when thus divided, are well known, and we see it applied in cases where transparency and a high power of refraction are required, such as in the doors of stoves and other similar positions; and attempts have been made to apply it to the manufacture of chimneys for lamps and gas burners, but with little success. M. Holthausen's new application is beginning to find its way into the shop windows of Paris, and to attract attention. He prints his designs on the mica in grey, and afterwards produces his effects by the use of transparent and opaque colours and metallic reflections. The use made of this new process has been as yet confined to the ornamentation of lamps and shop windows, but it is proposed to apply it to the production of a cheap substitute for stained glass. The sheets of mica can be painted in any required manner, and the work preserved, it is said, by means of a varnish, or the painting may be fixed like enamel on the mica by the use of different pigments and the aid of a furnace, the pieces of painted mica being afterwards fixed, with the coloured side within, on the glass of the windows. The mode of proceeding is thus described:—After the mica is split into laminae and trimmed into shape it is glued down upon cardboard to be polished and printed. The former operation is performed by means of a soft rubber moistened with a solution of soap or sulphuric acid extremely diluted with gum-water; the printing is performed in the ordinary manner or by transfer, in order to present the design in the natural position so as to be seen by transparency. Opaqueness is produced by a previous coat of varnish or a metallic ground obtained by means of leaf or powder. The colours are laid on as in illuminated works, and the ordinary pigments may be employed, and afterwards covered with a transparent spirit varnish; or, as before stated, enamel colours may be used and the sheets passed through the fire. It is admitted, however, that in the latter case one great advantage of the process, namely, cheapness, is in a great measure sacrificed. When the ornamentation is completed the mica is removed from the card and fixed on glass, or any other substance, by means of a solution of gum sandrac, and mastic, in potash and alcohol. It is said that, with ordinary care, the junction of the pieces of mica in a mosaic or other work is quite imperceptible, so that, in the case of a painted window, there is no other limit but the size of the glass on which the mica is fixed. Whether church windows will ever be executed in micagraphy may be open to much question, but the use of mica as an inexpensive means of ornamentation may be very acceptable.

Commerce.

FRENCH LIFE-BOAT ASSOCIATION.—The English association for the saving of life from shipwreck has always

been looked upon with great admiration in France. There exist in most of the French seaports, local associations for the same benevolent purpose, but they are crippled in their means, and have no organisation among themselves. M. Th. Gudin, the marine painter, whose brother was lost at sea, has long striven to establish a central association in France on the plan of the English society, and the Imperial Government has authorised him to proceed with the good work. A number of admirals, captains of the navy, and rich ship owners, have become patrons of the new association, and Baron de Rothschild and M. Donon have undertaken the care of the funds, and M. Delvigne, the inventor of the porte-amarras, or life-line, is named secretary. The carrying out of this desirable object may be attributed in a very great degree to the excellent articles by M. Alphonse Esquiros on the life-boats and other means of saving life in use on the coasts of the United Kingdom.

Colonies.

LAND IN VICTORIA.—A return laid before the colonial Legislative Assembly shows that there are in Victoria 1,166 pastoral runs, occupying, at the time of the passing of the Duffy Land Act, an area of 31,785,468 acres, and producing a rental of £225,118 17s. 7d., or an average of little more than 1½d. per acre. As many as 89 runs, occupying an area of 6,277,340 acres, produce less than ½d. per acre. Since 1862, 364 of these runs have been transferred, and 1,311,469 acres embraced in them have been alienated. As many as 70 runs, extending over 3,748,593 acres, have been forfeited under the provisions of the Land Act of 1862. In addition to the above, there are 16 runs, occupying 345,604 acres, the arrear rent of which has not been satisfactorily determined. The number of licenses issued to pastoral tenants for grazing purposes during the past year is 1,172, the number of persons to whom the same have been issued is 737, and the extent of land held under such licenses for grazing purposes is 30,722,886 acres.

AUSTRALIAN COMPANIES.—A prospectus of a new company, called the Pastoral Loan Company of Australia, has been issued. The objects of this company are to make advances on all descriptions of pastoral property in the Australian colonies, and also to purchase and sell such property if necessary, and to carry on all kinds of mercantile operations and agency incidental to such business. The capital is £250,000, in 25,000 shares of £10 each. The provisional committee comprises the names of several influential gentlemen connected with mercantile and pastoral pursuits, who are prepared to take up 10,000 shares. A prospectus of a new steam company, called the Clarence River New Steam Navigation Company, has also been issued. The capital is £30,000, in 6,000 shares of £5 each. Three-fourths of the shares are to be reserved for allotment amongst the inhabitants of the Clarence and Richmond and New England districts.

NEW ZEALAND RAILWAY FROM DUNEDIN TO PORT CHALMERS.—It appears from the Otago papers that the provincial Government have received overtures for the formation in England of a company for the construction of this railway. There is a strong probability that the company will be formed.

NEW ZEALAND GOLD.—The gold-fields of the province are progressing most satisfactorily. From the Upper and Lower Buller the accounts are of a very encouraging description; and although there have not been any large finds, the men are all satisfied with the returns. From the Grey the last accounts were also favourable, the steamer *Nelson* having brought up nearly 700 ounces, most of which was purchased in a week.

NEW ZEALAND COAL.—The coal beds at Motupip which for some time have lain neglected, are again about to be turned to account, operations having been com-

menced there. Instead of seeking to procure coal of inferior quality, obtained at or near the surface, an effort has been made, by deeper workings, to reach the coal in a more compact and pure state, and it is satisfactory to find that this has been attended with very great success. It is the intention of the lessees of the Motupipi coal-field to ship coal regularly to Nelson and sell it at a price which will enable them to compete successfully with coal from Australia. This coal has been successfully tried for steam purposes. The consumption is rather greater than that of Newcastle coal, but as the price of this coal is only about two-thirds that of Newcastle coal, it is more economical, while it otherwise answers exceedingly well. No difficulty has been found in getting up steam with it.

STEAMERS IN SOUTH AUSTRALIA.—There has been launched a new steamer, owned by the Murray River Steam Navigation Company, being the first of a line of steamers intended to ply on the Murray and its tributaries. It is built on the iron and wood principle combined, having an angle iron for the timbers, and Oregon pine for planking, which makes very strong and substantial work, is much lighter and neater than wood framing, thus securing a much greater degree of safety to a cargo, for if one of the compartments were to get filled with water, the vessel would still float, with no damage to the goods in the other compartments. Both engines and boiler were manufactured in Melbourne, and are said to be of first class workmanship. The dimensions are, length, 85 feet, beam, 15 feet, and she is expected to be a very fast boat. The company intend building other vessels of light draught and great speed.

Obituary.

ROBERT LUCAS CHANCE, sen., of Summerfield, Birmingham, died on Tuesday, the 7th March, at Northfleet House, near Gravesend, in his eighty-third year. Mr. Chance belonged to one of the oldest and best-known families engaged in trade at Birmingham, where he was originally in business, with his father and brothers, as factors. Afterwards he came to London, and established himself in the glass trade; but, returning to Birmingham thirty years ago, he has ever since been closely identified with the rise and success of the great firm of Chance Brothers and Co., at Spon-lane, in which, up to his death, he was the senior partner. It was to his remarkable ability, far-sighted enterprise, sound judgment, and unwearied industry, that the progress of that house is greatly due. In 1861 it was owing to his firm that the glass for the erection of the Exhibition building was produced. At that time there was no firm existing in this country capable of producing the glass of the size and weight required under the contract, within the time specified, and had it not been for his capital and enterprising spirit, the work could not have been carried out. The microscopist is indebted to him for the thin glass for mounting his objects, and he did much for the improvement of glass for optical purposes, as well as for the large construction of lighthouse lenses, in which he competed successfully with the French manufacturers. Partly on account of deafness, and partly from his habit of mind, Mr. Chance avoided all public business. But there was one great duty which few men have more thoroughly or unostentatiously discharged; on a settled principle of benevolence, and as a point of conscience, he acted rather as the steward than as the owner of his well-earned wealth. His public munificence, great as it was, relatively bore a small proportion to his private beneficence. He possessed a keen insight into the questions which from time to time have occupied the attention of cultivated men. He had read much and thought deeply; and, gifted with wonderful energy of mind, seasoned with a shrewd though kindly humour, he had a way of ex-

pressing his opinions which impressed them with singular force upon the memories of his auditors. In all that had relation to politics and religion, Mr. Chance was broadly Liberal, in the best sense of the word. Though not a member of the Church of England, he was entirely free from sectarian bitterness, and always spoke of the Church and of Churchmen with the greatest respect. As one of the founders and warmest supporters of the Edghaston Proprietary School, he illustrated by his conduct his settled conviction that religious and secular education should be entirely separated.

The death of Sir ROBERT HERMANN SCHOMBURGK, the eminent traveller, took place at Berlin on the 11th inst. Sir Robert was born in 1804. In the years 1835 to 1839 he undertook expeditions in British Guiana, under the auspices of the Geographical Society of London; and in the years 1840 to 1844 extended these explorations as Her Majesty's Commissioner for surveying the boundaries of British Guiana, between Brazil and Venezuela. On this occasion, after enduring much fatigue and great privations, with his small party, he completed the circuit of the colony, from its sea boundary to within forty-two miles of the equator, in the course of about three years. For these labours he was knighted by Her Majesty. During his expedition he discovered and introduced into Europe the well-known water lily the *Victoria regia*, which he assumed for his crest. Sir Robert was also made a Knight of the Royal Prussian order of the Red Eagle, of the Royal Saxon Order of Merit, of the French Legion of Honor and a corresponding member of the Royal Geographical, Zoological, and Entomological Societies of London, and of many foreign scientific societies. He was a frequent contributor to the leading scientific periodicals of the day, and to the proceedings of the British Association; and among other of his published works may be mentioned "A Description of British Guiana," "The History of Barbados," "Views in the Interior of Guiana," and "Reisen in British Guiana in der Jahren, 1840-44." Sir Robert filled the posts of British Consul General in San Domingo and Siam, and he only returned from Bangkok at the close of last year. His funeral was attended by a large number of scientific men.

Notes.

STATISTICS OF PARIS.—The population of Paris at the end of 1863, according to the *Annuaire of the Bureau des Longitudes* for 1865, numbered 1,667,841, or, with the garrison, 1,969,141. The excess of births over deaths was 11,485. The number of marriages 16,485. The births numbered 54,077, viz., 27,634 males, and 26,443 females; of this number 6,262 were born in the various hospitals, and 15,259 were illegitimate, of which number, 3,706 were recognized by the parents, according to the law in force in France. Of the 42,562 deaths, 10,975 occurred in the civil, and 647 in the military hospitals, and 114 in prison. The number taken to the Morgue was 346, of which 61 were not recognised, or not claimed by their family or friends. It is a curious fact that the number of deaths from small pox was just ten more than that of the suicides and accidents recorded at the Morgue. In the whole of France there were just over a million of births during the year, of which 76,697 were illegitimate. The excess of births over deaths was 188,481 only. The Parisians consumed during the year about sixty millions of gallons of wine, something less than an average of a pint per head daily, and nearly eight millions of gallons of beer; 333,342 tons of butchers' meat, 1,764 of charcuterie, sausages, and other compounds of the same class; nearly 183 tons of pâtés, small shell fish, truffles, &c.; 2,969 tons of cheese; oysters to the value of £106,000 odd; fish to the extent of £475,427; poultry and game equal to £871,769; butter representing nearly a million and a

quarter sterling; and eggs more than half that sum. They burned 639,963 tons of coal, coke, and carbonized peat, and upwards of 13,000,000 bushels of charcoal. They used nearly 6,746 tons of ice; and 11,386 tons of salt, white and gray.

A PEOPLE'S PARK IN PARIS.—One of the rudest spots in the environs of Paris, the Buttes Chaumont, where for hundreds of years the quarries for the plaster of Paris have been worked, is being converted into a public garden and promenade. The new park will cover about sixty acres of ground, and the total cost, including the indemnities, will amount, it is said, to about £300,000.

SCIENTIFIC ASSOCIATION OF PARIS.—This new society, headed by the Imperial Astronomer, exhibits great energy; it commenced by the application of a sum equal to £2,000, for the construction of large astronomical instruments for observations in the provinces; next it devoted £320 to prizes for meteorological studies; and it has just authorized a committee of its council to draw up a scheme for the employment of a sum of £240 in the encouragement of physical sciences. The committee has made its report, which has been adopted by the council. The sum of a thousand francs is devoted to an inquiry, to be made by M. Camin, professor in the Lycée of Versailles, into the dynamic theory of heat. Another sum of 700 francs is to be placed at the disposal of M. A. Terquem, of Metz, for the apparatus necessary to work out his theory of the vibrations of plates, rods, and cords; the apparatus to remain the property of the association. A third sum of 500 francs is devoted to the purchase of a spectroscope; and a collection of crystals, prisms, and lenses, to be placed at the disposition of M. Geniez, of Dijon, for examination into the rotatory power of quartz in high temperatures. Two further sums, each of 500 francs, are to be given to M. Guggis and M. Dinnon, to assist those gentlemen in their researches in electricity and the spectrum analysis. It is hoped that next year the association will be able greatly to extend its operations.

Correspondent.

NEW ROOTS TO OLD TREES.—SIR,—The paragraph in the last *Journal* on the removal of old fruit trees, by which it appears that a French horticulturist puts a new tree to the old roots, reminds me of a plan rewarded by this Society in 1843, by which Mr. John Common put new roots to old trees. It is described in volume 55 of the Society's *Transactions*, p. 3, as follows:—"The plan of putting new roots on trees, and taking away all the old ones, is of great utility, for I know by experience that trees are often engrafted on, which, on account of their roots, will not allow the trees to bear the proper quantity of fruit; and the plan of putting new branches on espaliers or wall-trees is also of great utility, as a branch is often wanted to finish the tree. This method of engrafting may be done at any time between April and August, and either with the present year's wood or with wood of several years' growth. The mode of effecting the addition of a branch to some particular part of the stem is by bending a branch either from the same tree or from some tree near to it, and inserting the end thereof behind the bark, which is properly cut to receive it, and then tying it carefully round with string, and it is more certain of taking hold or growing than by any other way of engrafting or budding, and as certain, or more certain, than by any other way of inarching. . . . The mode of procedure in this novel operation, if the tree be small, is to plant a small tree close to it, inarching it as already mentioned, by bending it over to the original tree, and tying it round as before. The planting of the new tree should be done in the spring, before the year in which the inarching is performed; and when from sufficient growth it has firmly taken hold the old root may be taken away. If the tree to be under-

pinned be of large size, then several small roots are to be planted around it, and each inarched, as already mentioned. When the new roots have strength to carry the tree, the old ones must be taken away by degrees, care being taken to make an incision all round the bark."—I am, &c., MEMOR.

CHEAP RESTAURANTS IN PARIS.—SIR,—These institutions continue to flourish in Paris. Being lately in that city I visited one several times. A capital breakfast can be had for 6d. or 8d.; a outlet and wine for 6½d. The places are tastefully decorated and clean. The attendance is given by a set of modest-looking women dressed like nuns, and altogether a luncheon in one of these establishments may well be recommended to every tourist, and he will not forget it. There are about a dozen of them in Paris, all thriving I believe. I enclose a specimen of the card which every one fills up.—I am, &c., FELIX SUMMERLY.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o’clock.

APRIL 5.—“On food for Cattle.” By Professor JOHN COLEMAN.

APRIL 12.—Passion Week. No MEETING.

CANTOR LECTURES.

The Third Course for the present Session will consist of six Lectures “On Some of the Most Important Chemical Discoveries made within the last Two Years,” to be delivered by Dr. F. F. GRACE CALVERT, F.R.S., F.C.S. (Corresponding Member of the Royal Academy of Turin ; of the Société Industrielle de Mulhouse ; of the Société Imperiale de Pharmacie de Paris, &c.), on Tuesday evenings, at Eight o’clock, as follows :—

APRIL 4TH.—LECTURE 1.—On the discoveries in Chemistry applied to Arts and Manufactures.

APRIL 18TH.—LECTURE 2.—On the Discoveries in Chemistry applied to Arts and Manufactures (*continued*).

APRIL 25TH.—LECTURE 3.—On the Discoveries in Agricultural Chemistry.

MAY 2ND.—LECTURE 4.—On the Discoveries in Physiological Chemistry.

MAY 9TH.—LECTURE 5.—On the Discoveries in the Chemistry of Rocks and Minerals.

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

Proceedings of the Society.

SEVENTEENTH ORDINARY MEETING.

Wednesday, March 29th, 1865 ; Sir Thomas Phillips, Q.C., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society :—

Austin, Charles E., 7, Broad-sanctuary, S.W.
Bradley, E. B., 1, Church-meadows, Sydenham, S.E.
Brown, George, Bruckwood-house, Croydon, S.
Buckney, Thomas, 12, Brunswick-square, Camberwell, S.
Canning, L., Abbey-wood, S.E.
Chambers, W. Oldham, Lowestoft.
Cook, Rev. John, Elm-grove, Southsea.
Costeker, John, St. John’s-hill, Wandsworth, S.W.
Da Silva, Johnson, Beach-house, Bognor.
Lasslett, Thomas, Devon-house, Maryon-road, Charlton, S.E.
Lewin, William Henry, 135, Southampton-street, Camberwell, S.
Lloyd, Percy, Ash-villa, Burnt-ash-lane, Lee, S.E.
Lucas, Charles, Royal Academy of Music, Tenterden-street, W.
Massey, Hugh H., 33, Camberwell-green, S.
McArthur, Alexander, Raleigh-hall, Brixton-rise, S.
McEwan, James, 38, Cannon-street, E.C.
Nagle, Rev. W., 1, Blackheath-villas, Blackheath, S.E.
Parker, Thomas, 10, Brunswick-square, Camberwell, S.

The following candidates were balloted for and duly elected members of the Society :—

Brandt, F. C. W., 3, Abchurch Chambers, Abchurch-lane, E.C.
Drake, Francis, Friar-lane, Leicester.
Jacobs, Lewis, 146, Strand, W.C.
Kiel, George Middleton, 16, Stanley-gardens, W.
Oakes, William Smith, Addison-road, Kensington, W.
Simes, N. Phillips, 58, Coleman-street, E.C.
Strachan, Mrs., Norfolk-house, Arundel-square, N.
Wilkin, Frederick, 10, Spring-gardens, S.W.

The Paper read was—

ON WINDOW HORTICULTURE, AND THE CULTIVATION OF PLANTS AND FLOWERS IN CITIES AND CROWDED LOCALITIES.

By JOHN BELL, Esq.

The insufficient dwellings of the poor, and the best mode of ameliorating them, have always formed one of the subjects to which this Society has been desirous to give its aid ; and, as you are aware, within these last two years a greater amount of action has been taken thereon. In harmony with this, the subject which I introduce to

you this evening may claim your indulgence, as, at any rate, in part directed to the same end. Flowers and plants at windows, and floriculture and horticulture in cities, may be equally pleasing to the rich as to the poor; but while to the former it is easy, by change of place and scene, to be, in brief space of time, amid the luxuriance of flowers in the country, the poor mechanic, resident in London, detained by his daily work, has not time, money, or opportunity for a similar change, and to him, in consequence, the few flowers and plants he can raise and see bloom under his own eye, if indeed only at his window, are proportionately dear, and indeed a treasure.

Amongst the revelations of the railways are those by which we look down upon the tops of houses in some of the poorer parts of London, and those inhabited much by the artisan and workman. As the train moves slowly in starting from or coming into this great town we have many of these glimpses into modes of life differing from those of the residents of other localities, and perhaps larger houses. Among the tastes that we see pre-eminently displayed here, are the love of birds and the love of flowers; and various are the expedients improvised, and of home manufacture, for the indulgence of these tastes and the accommodation of either class of natural history. With the pigeons and canaries, on the present occasion, we have nothing to do, but as regards the accommodation of flowers and plants, we may well remark the variety of expedients to which the love of Nature, and at the same time the narrowness of space and means, drive the enthusiast. Tubs, pails, baskets, crockery of many kinds, troughs, glasses, bottles, and almost every kind of receptacle are enlisted in the service of his taste and the worship of Flora; and in more than one ambitious instance I have seen the top of some small outbuilding covered with a layer of earth, for the accommodation of flowers and shrubs, and fenced round with boards and slates on end, to keep them in their place within their narrow bounds.

This last-mentioned arrangement, indeed, seems, on a very small scale, to be similar to that which the celebrated hanging gardens of the city of Nineveh exhibited on a very large one so many hundred years ago. Of those famous gardens the old historian Diodorus Siculus gives us an account, not very much to the purpose, inasmuch as he left all the world much in doubt what they were. But of late years, since the discoveries which have taken place in and about ancient Nineveh, more light seems thrown on the subject, illustrating the mode in which they were really constructed. Earth was laid on in a stratum of not less than six feet in thickness, with no doubt good arrangements for drainage beneath; this mass and extent of elevated earth was apparently treated in all other respects just as a garden on the level of the ground, having been planted with trees and laid out into parterres with walks intervening, where the monarch and his court, or the priests and their devotees could promenade in shade and elevated seclusion, and enjoy the prospect over the wide valley of the Tigris. It may be remarked, *en passant*, that the depth of the soil of these gardens is further and happily illustrated by the service they have rendered to history and art; for when the great fire took place on the capture of the city, 600 years B.C., the upper stories of the architecture being of wood, were easily burnt, and the superincumbent gardens fell in a mass, covering up at once the elaborately sculptured walls of the basement, thereby not only at the time protecting them from the hand of the invading armies, but in great measure for centuries to come, from the still more destructive hand of Time, as is visible in the remarkable freshness of many of these most valuable historic works of art, as now seen in the British Museum after a lapse of more than 2,400 years.

Far removed as these incidents are from us in time and place, they are not without their immediate familiar interest with us as regards the present subject, as they afford the earliest example on record of town gardening in connection with architecture, and that in relation with one of

the most celebrated and populous cities of ancient time. In considering this, it is evident that in that warm climate these gardens answered two purposes, not only that of a charming and most private resort, not overlooked from any adjacent spot, and at the same time enjoying whatever breeze there might be stirring, as well as an extended prospect; but also, at the same time, they provided for the coolness of the apartments beneath in the same manner as the inhabitant of the same region now shields his head from the rays of the sun by the multiplied folds of his turban. In this climate we have certainly not all the same reasons for masses of earth on the tops of our houses; but I confess I cannot see why something of the same sort might not, as regards growth of plants, be adopted occasionally in our cities, by making the top story with a glass roof instead of a slate one, by which means we might obtain above our attics an additional apartment or apartments of a greenhouse character, where plants might be grown in much perfection, and which at the same time would be available for workrooms of various kinds, for artists' studios, and for many of the purposes requiring light in this great busy city; for it may be remarked that that compound nebula, a London fog, though deep in colour is not so as a stratum; it lessens rapidly in density as you ascend, although it has occasionally almost a definite top-surface to it, above which all is bright. For instance, I have had an acquaintance of some years standing with a thrush in Kensington-gardens, who has a fine flow of spirits, for he sings nearly all the year round. He affects one particular tree, on the top of which, when I have been walking below in the dense fog of November, I have heard him up above on his branch, in the clear sunshine, warbling away in the fullness of his fruity notes. Individually, I may say, that if I had to build my own house over again, I would adopt this arrangement of a greenhouse upper story. I can hardly think but that in this great town, where so many ideas are realized, this has not been one of them, although I have never heard of it as a system, which I now submit to the indulgence of the architects of the time.

Following the ancient period above mentioned—for these gardens of Nineveh were destroyed 150 years before the Parthenon was begun—the Greek exercised his native taste in the association of gardens with architecture. I have not space to detail what is known of these, and will only quote one passage from an interesting paper on the "gardens of the Greeks," in *Chambers's Journal*, for August 31st, of last year. The author there says as follows:—"When the Greek was shut up hopelessly in a city, he created on his window ledge a garden for himself, either, if rich, in a silver basket, sculptured all over with rustic imagery, or, if poor, in one of wood or osier, where he fostered and allured into bloom the denizens of distant mountains and valleys." He adds, *en passant*, "At any rate, no people but the English have ever been fonder than the Athenians of rural architecture."

From the Greeks we naturally come down later to the Romans, who had a special phrase for this introduction of Nature into towns (now somewhat hacknied by much use) of "*Rus in urbe*;" and this was much realised in Rome, where the advantage of "*Open spaces*" was as highly appreciated as with us, and where the great did service to the people by the appropriation of large gardens for their recreation. As far as we learn, however, from the domestic records of Rome, this "*Rus in urbe*" was not confined to public places in that city, nor an empty phrase even as applied to domestic residences, but the divinities of gardens were among the Roman's most cherished household gods, no home being complete without a garden, though it might be a small one, the kind of pretty little household garden which was considered a requisite adjunct to a residence of taste being very well illustrated in the Pompeian house in the Crystal Palace.

Household gardening also is illustrated in the arrangements of the Alhambra; and the Turks, Persians, and Chinese all favour gardens in connection with their city

dwellings. Indeed, it may be said that this taste, to a greater or less degree, accompanies civilization and refinement among all nations. I daresay, however, that all will agree with the remark in *Chambers*, that, at any rate, no people are greater lovers of Nature than the English at the present time, and that although, in the scientific treatment of subjects of natural history, other nations may be, in some points at least, our equals, yet, in the general popular love of natural history in its varied forms as existing in the heart of the people, it is not too much to say that the inhabitants of no country are so thoroughly imbued with it as the English man, boy, woman, girl, and child. In illustration of this, the popular books on these subjects for all ages, published annually in London, outnumber, I hear, those published in all the rest of the world together; the bearing of which being that, in affording facilities for the cultivation of a taste for Nature in one of its most elegant departments, that of the growth of flowers, they are not likely in this town to fall on barren ground. It must, indeed, be acknowledged that the quiet excitement of tending plants and seeing them grow, is all good—it has no bad side. It is an excitement without reaction, and so a healthy one. It is a phrase that “cleanliness is next to godliness,” and it may be added that the love of flowers is akin to cleanliness, and so but one remove, at least, from godliness. In a charming little book by the Rev. Haddon Parkes, formerly of Bloomsbury, now of Putney, they are associated together. The title is “Window-gardens for the people, and clean and tidy rooms;” and various of the facts contained in it illustrate the relation of the three qualities.

Thus helping the sentiment for the cultivation of flowers, seems helping the good side of human nature. I met with a pleasing remark some time ago, in a book of travels in the North, entitled “Through Norway with a Knapsack,” in which, as a pedestrian wayfarer, on the humble footing, to which he had restricted himself in his tour, the author, Mr. Williams, had to find lodgings in strange cities and out-of-the-way places, and his remark is to the effect that he found no surer guide to the houses of good, kindly, cleanly, and honest people, than the presence of flowers at their windows, inasmuch that at last he took these simple signs of Nature as his clue to a friendly welcome, a clean bed, and an honest bill in the morning. I find that Mr. Parkes quotes an observation to a similar purport by Erskine Clarke, that “flowers growing in the window sills of the poor are one of the safest indications of a well-ordered and cheerful interior, and that they are among the most reliable of advertisements;” and Mr. Parkes adds, “it is well known that in large towns, such as Sheffield, Birmingham, Manchester, and Coventry, those who cultivated flowers partly from the love of them and partly because a knowledge of them is necessary to their calling in life, are amongst the most skilful, industrious, and exemplary of workmen.”

I do not enter upon the chemical question, as to the effect of plants upon the sanitary condition of rooms. I leave this question to those who have studied it; I have not. I hope there may be some one in this room who can treat this point, and will favour us with his remarks. I know it used to be said that flowers and plants were injurious in sleeping-rooms, which the workman's living-rooms frequently are. Of late, I understand, a different opinion has arisen, that the presence of flowers is advantageous. I hope it is so, for I am glad of everything that can be said for flowers. At any rate, however, nothing can be said against flowers outside of the window. Flowers at an open window, either for sight or fragrance, cannot but be healthy, and this I conceive to be in general the best place for them.

It must not be supposed, however, that I fancy myself a pioneer on this subject. Others have been before me whom I am only happy to follow so as to contribute my mite of experience. But having been a window gardener for some years in a suburb of London, my success leads me to think that domestic gardening of that kind is only in its

infancy; an art which derives its great interest from its being available where no other gardening is—to the artisan of the metropolis, in the most crowded parts of which ground is let, as it were, by the square inch, and is too valuable to be expended in space for gardens. Besides, in places where the houses are close and high, plants will scarcely grow better at the level of the ground than at the bottom of a mine. To this point, in the *Gardener's Chronicle* of May 14th of last year, Miss Maling draws attention. “First, then,” says this authoress, “we must remember the incalculable advantage to all town and London-grown plants of being lifted up from the ground. The first time I tried the plan myself it was that there was a back garden, deep down and well-like, in which not a thing would grow. A little breakfast-room looked out upon this ‘dampery,’ and there I got my boxes fixed, raised above the level of the surrounding walls, the plants enjoying the free current of air that now passed around them. The way in which that garden thrived attached me for life to this plan. The soot and smoke may be bad in towns, but that I do not think is the real grievance. They can, after all, be washed off. It is the stagnant air, or the no light in some cases, the scorching sun in others, that stunts and kills town plants.”

Now as the artisan in London seldom occupies a whole house, it is rarely but of a window or two that he is lord and master, and thus his gardening in town must be more or less in such situations; thus the prizes which have been offered for the growth of flowers in London have been chiefly responded to from windows. In more than one parish has this been the case, that which rejoices in the happy name of Bloomsbury being, I believe, the foremost. Here the subject has met with sundry supporters, and under the auspices of the incumbent, the Rev. Emilius Bayley, and the Rev. Haddon Parkes, many rewards have been distributed among the poorer classes for the growth of plants, chiefly as above mentioned, in that and adjoining parishes.

From the little work published last year on this subject by the latter gentleman, I shall venture to quote largely, in proportion to my own remarks; my own especial practical mission, I may as well say, having been rather the suggestion of mechanical means for facilitating such open-air town gardening and the testing them myself by the growth of seeds and flowers in them for the last three years, than any higher or more philanthropic fostering of this most civilizing and cheering taste.

With this parenthesis, and turning to the directions of Mr. Parkes upon this branch of horticulture in cities, I would express my own belief with his, that in the upper stratum of air at windows even in the midst of London, at the present time, many flowers will grow well with care and proper appliances. The prizes given at the Bloomsbury Shows, for flowers grown within the parish, were chiefly for fuchsias, geraniums, and annuals. Mr. Parkes, in his account of them, says that competition was confined to these because they are inexpensive and easy to procure, but adds that experience has shown that many others than those named can be successfully cultivated in London by the poor; he mentions occasional syringing or careful washing of the leaves of the plants, which are their lungs, from the smoke or dust, as of much benefit to them.

With a view to give a sketch list of such plants as may give response to the care bestowed on them, I have put together such from various sources, from the suggestions of Miss Maling and Mr. Eyles, the superintendent of the Royal Horticultural Gardens, in Kensington, as well as from those of the Rev. Haddon Parkes and from my own trials—any shortcomings in the list are, doubtless, my own:—Fuchsias and pelargoniums of most kinds, window balm (which bears small lilac flowers in August), lavender, thyme, bergamot, southernwood—that is “old man,” as it is often called, which does pretty well everywhere, and is very pleasantly aromatic. The yellow and white stone crop also grow well, but

the pink requires a free mountain air. Creeping Jenny is a kindly flower, with its little yellow blossoms at every joint, and does well almost everywhere. Candy tuft also is easy of growth; also the common British aloe (or house-leek). This has the same habit of flowering as the other aloes—that is, only occasionally—so that, out of a large family group of star-like plants, only one or two, perhaps, will shoot forth their tall flowers in a season. Of this household plant, Gerard, in his "Herbal," speaks very highly for the cooling virtues in medicine, as in healing green wounds, &c., and it is even now thus used in some parts of the country. Apropos of this, we may call to mind that this same old John Gerard, who was so much respected for his botanical lore in his own time, and so deservedly even now, lived in Holborn, and in his large "Herbal," or book of plants, he dates his address to his readers—"From my house in Holborne, this first of December, 1597;" where, also, he had his garden.

The golden Marys, or marigolds, as they are commonly called, do well, but are rather pale if they have not plenty of sunshine. The daisy, or day's eye, from whence its name so familiar to us, does well for one season. As a passing observation, we may see how peculiarly happy is this name, for even when the flower is closed, its delicate petals lap over, like eyelashes. Also the pansies, so called from the French "*pensées*," or thoughts. Also *mignonette*, which, although we call it thus in French, *mignonette*, or "little dear," in France is called "*reseda*." Wallflowers do well; also Virginia stock; and the gazania; also sweet William pretty well; also, for a season, primroses of the various kinds, and most hardy annuals will come up from seed and bloom where the air is pretty free and there is sunshine.

As regards shrubs, the original old English evergreen of our forefathers, now of late years again come into fashion, the *phyllarea*, or British olive, does well; also the *aucuba japonica*, *pyrus japonica*, and *genista*, and even the golden furze or whins of the wild heath will bloom sometimes surprisingly well in our metropolitan atmosphere. Also may be added to this flower list—*chrysanthemums*, *lobelias* and *verbenas* of most kinds, including the lemon-plant, the *anemone*, *canariensis*, *ipomea*, *tropaeolum*, *clematis*, sweet pea, also the bindweeds or *convulvi*, larger and less; also *nasturtiums* exceedingly well, both the dwarf and other kinds. These may be raised from seeds in the spring or by cuttings later in the year. The flowers of this plant are very pleasant as to both eye and taste, introduced in salads, as well as the seeds for pickle. If sown it should be in April.

Mustard and cress, as well as musk, of course do well; also *calceolarias*—the common kinds, and *heliotropes* pretty well; also *cinerarias*; also ivy, of course, and Virginian creeper; also ferns of most common kinds, if carefully syringed and washed. Crocuses and snowdrops, and all the early bulbs, do well, but are late in exposed situations; perhaps of all these none are more likely to answer than the early tulip. I have also found the scarlet-runner do well in this situation. These plants are grown in some places only for their beautiful flowers, as in parts of America and Scotland, but here they are chiefly used for the table. Thus they have a double claim to our esteem.

The above list I have ventured to give only for revision, and I would add that it is only experience that teaches us the most available plants for city household horticulture and the best means of managing them. I would add that of all the geranium kind the common horseshoe-leaved variety is that which Mr. Parkes speaks of as having flourished best in Bloomsbury and St. Giles's. I cannot leave what this gentleman says without further quoting him in respect to the benefit which he speaks of as having accrued to the poor of these localities by the fostering of their natural love for flowers. "Many instances," he says, "of the way in which this love for flowers evinced itself came under my notice, and

I will mention two or three as illustrations of the strength of this love as proved by the efforts made by individuals. A poor man, living in a close little back room on the third floor, and eking out a wretched existence by ill-paid army work, transformed an old fish-basket into a small garden. In this he had sown a few simple annuals, but they were all so well grown and so tastefully arranged, that Mr. Sowerby, the judge at the Russell-square Flower Show, specially recommended them for an extra prize. A poor widow, living in a back cellar, into which the sunshine came only for one hour in the day, anxiously watched for that hour to come round, in the hope that her geranium might have every chance. The result of all this care was not very encouraging, for the plant only just lived and never attempted to flower. But yet it was a great comfort, notwithstanding, to this poor woman. She said to Mr. Parkes, 'I never thought before that a flower would live in my room. I did not believe before that I should ever care for anything again in this world like as I have cared for that geranium. Indeed, sir, I've got almost to love it as if it could speak.'

"A poor man, into whose room sunshine never came, with a zeal and energy worthy of praise, made an ambitious attempt at a conservatory by means of an old orange box, and a second-hand window sash, which he nailed against the wall of the back-yard of the premises in which he lived, and exhibited some very creditable specimens of plants grown under difficulties.

"There was living, at the time of the first flower show, an old man, whom no one could induce to leave his room. The clergyman, the Scripture-reader, and the City missionary had all failed to move him, and their arguments were as nothing to him. He had lived so long in seclusion, that, as he said, 'he was ashamed to be seen in the street, the people would all stare at him so;' and so strong a hold had this strange feeling on him, that for years he had not crossed the threshold. A plant was given him, in the faint hope that it might supply him with a fresh interest in life. He was greatly pleased, and bestowed much care and attention upon it, and at the time of the show brought it in his own hands to the room, saying that he would not trust it to the care of any one else. He had a prize, and, to the surprise of us all, without any personal solicitation, he afterwards presented himself at the Sunday evening service, and became a regular attendant there.

"Other instances might easily be produced to show the individual interest which was taken, but enough has been said to prove this. At the workmen's club it was an absorbing topic; a rivalry was established between certain members of the club. Geraniums were matched against geraniums for the prize, and annuals against annuals; and the best mode to water the soil and wash the leaves of the plants was a frequent subject of discussion. One man had the temerity to say that he could grow a cauliflower, and that before another show he would make the attempt. After the last exhibition the members of the workmen's club were so satisfied with their powers as flower-growers, that they said they were willing to grow flowers against any other club of working men in London. No one, I think," adds the author, "with these facts before him, can doubt that, whether we look at the general results of the flower shows or the individual interest as proved by these examples, there is a real love of flowers among the working classes of London." No doubt, indeed, this taste may be said to be innate in nearly all. Bacon, Lord Verulam, who is so good an exponent in few words of large facts, says that the "Almighty first planted a garden," and "that it is the purest of human pleasures," adding, "that it is the greatest refreshment to the spirit of man, without which buildings and palaces are but gross handiworks." Thus does the philosopher express not only the universality and propriety of the taste for horticulture, but also suggests indirectly its familiar association with architecture.

The love of flowers among the richer classes in London

is evident enough. Rarely do you enter a large house without seeing proof of it. And we may be certain also that it would be more frequent than it is in the dwellings of the poorer and working classes had they improved facilities for it. Moreover, there are the Soldiers and Sailors. I have heard that the first fuchsia seen in this country was discovered in a pot at the window of a sailor's wife in one of the semi-marine regions of Wapping or Rotherhithe, by some wandering and wondering botanist, whose steps chance had led that way. Even if in the particular instance of this beautiful plant this be a myth, yet I believe I am not in error in saying that for many valuable early introductions into this country from foreign parts of beautiful and useful plants, we have been indebted to our sailors. Might it not be then but fair for us to see if, wherever there are poor sailors' homes, either on water or on land, we might not offer them facilities for flower growth, and perhaps encourage them by prizes?

Also in respect to the sister service, the army, I do not know any class to whom facilities for the gratification of this taste would be more welcome. It has been suggested to me by a good military authority that many of the soldiers might like to grow mustard and cress at their barrack windows in preference to flowers. I am not so sure of this. But if it were so, no matter. There is a charm even in watching so simple an operation of nature as the development of a cress-seed into a plant, and none the less so because the plant responds in food as amusement. And this amusement is of a home-like character, and might well lend a relief to the monotony of a barrack life. At the windows of some of the barracks in London are accordingly to be noticed expedients for the growth of flowers. It has been suggested to me again that these perhaps are the windows of non-commissioned officers. They possibly have the most leisure, but window gardening is just one of those things that take no appreciable time, and I believe in the almost universality of the taste without reference to station. The existence of this taste among those of whom by far the largest part have formerly been private soldiers (I mean the Chelsea pensioners), is to be seen in the garden plots they occupy in the grounds of Chelsea Hospital.

The part of London around that institution has been much improved of late, and no pleasanter Sunday afternoon may be spent than by going first to the chapel service at three o'clock, where the old pensioners form the larger portion of the congregation, over whose heads hang the banners battered in many a conflict, and after service strolling in the large and varied grounds belonging to the Hospital, which have been laid out with much taste. One thing I am sorry for, viz., that the plots allotted to the old pensioners have been removed from their original situation to a part less favourable to them; but still they form to me the most interesting part of the whole grounds. These little allotments of garden ground are between five and six yards square each of them, and it is entertaining to see the variety of treatment they display. In some you see a little hut built as a garden seat; in others, an improvised greenhouse; in others, monumental trophies, grotesque heads, and plaster casts, are interspersed in the borders. Some are utilitarian, and grow vegetables; others ornamental, and devoted to flowers, and most combine both. Among them were several plots for the raising of musk plants, and, as respects one plot, I was informed that the season before, by the careful management of the occupant, he had realised £6. The embryo or young musk requires much care during the winter to ensure its early growth. This plot was so arranged that in the spring, when the street hawkers of musk came to buy it, it could be easily removed with the layer of earth in which it grew without disturbance to the roots, which is a great point, as I was told by a cheerful old pensioner I met there, who was my ready informant, but not the tenant of the plot in question. And I have been further informed that at one time the chief supply to London of musk plants was from the little plots of these

old soldiers; and even now that musk has become a much commoner plant, and there many other sources of supply, their occupation in this way is not quite gone. These evidences, however, are enough to show that the love of flowers and gardening is anything but dead in the soldier's heart, and some encouragement would doubtless give it fresh vitality.

I also met lately in a report of the gardening of some of our regiments in India, that the men were very readily pleased with that occupation when the gardens were near, but that they did not like to go far to them. But here they might have them in miniature at their barrack windows, where, as in cities, no other space could be afforded them. I am glad thus to see in the almanack sheet and programme of proceedings for this year of the Royal Horticultural Society in Kensington, of which I have the pleasure and amusement to be a member and neighbour, that prizes are offered to both sailors and soldiers for the growth of flowers. The area of such encouragement might be further extended, as to almshouses, model lodging-houses, and the convalescent wards of hospitals; and if, in the first instance, in the construction of these and of barracks, it were to enter into the plan to provide facilities for such domestic growth of plants at elevations, especially at windows, accommodation might be easily ensured for much larger masses of earth than have hitherto been attainable, and with excellent architectural effect, in which the string courses, for instance, might take up and continue the line of structural fixtures necessary for the receptacles in question. I think, also, that if we look back for a few years, we may perceive that the public taste has been going in the direction of freer and larger accommodation for flowers in connection with dwellings. Formerly a few separate pots of flowers were all we saw at windows, confined by perhaps a bar of iron for safety. Then came the wooden mignonette and flower boxes, which now for some years we have seen in terra-cotta also, prettily wrought. And now we find commonly about in the best parts of London receptacles of a larger size and more elaborate decoration on the window sills of our largest houses, and faced with the beautiful tiles of Messrs. Minton and others of our best manufacturers. Having myself been for some years a window gardener, and my plants thriving better at my windows than in my garden below, it naturally suggested itself to me to provide receptacles of a still larger size, and my windows being French casements, opening outwards, I could not have them on the sills. I therefore projected these receptacles further out, and so that the top of the earth contained in them should be level with and not above the sills. I had these made in iron by the Coalbrookdale Iron Company, so as to contain as much as two barrowfuls of garden mould, besides two inches in depth of fragments of flowerpots broken small for drainage. These are capable of perfect support by various means, as I have tested; but I think the best and completest is where the receptacle or "window garden" is made in one casting with the window-sill, which, being let or fixed into the brickwork at the base of the window, like other window-sills, only a little further in, the whole affair becomes perfectly self-supporting to the extent of five times the weight of earth that can be put in it. By this means, also, no damp can enter the wall, and the drainage is provided for. Practically there is no appreciable drip, the mass of earth, in common cases, absorbing and evaporating the moisture. But in the case of ferns, and any plants requiring a superabundance of moisture, two little sixpenny tins, of appropriate shape, hung over the sides, catch the drip from the two drainage holes, which are amply sufficient, inasmuch as there are two inches of drainage all over the bottom of the window-garden, as mentioned above, which runs off the superabundance into the drainage tins, which may thus, from time to time, be again emptied into the window-garden. These also evidently afford safety at nursery windows; they are capable of being glazed wholly up the window, or partly up, as may be

seen in front of a house in Piccadilly, and they might be even heated by pipes, &c., &c., but in all cases evidently the first point is to obtain a firm substructure and support.

In this kind of iron window-garden I have had much success in raising plants and flowers from seed in the usual way, and also when bedded out, when they have thriven with marked luxuriance; and this not only at my own house, but in some experimental receptacles in the Royal Horticultural Gardens last year, during which the same flowers flourished, without renewal, throughout the season, until late in the autumn, and although they were raised but a few feet from the ground, yet, from some unexplained cause, the growth and bloom of the plants and flowers in them was much superior to that of similar kinds near them, growing in the usual way in the earth. Whether this was owing to a greater amount of air getting to the roots of the plants in the window-gardens, and so stimulating them, I know not, but this difference of luxuriance, and continuance of bloom, was remarked by many. The plants in question were chiefly *deutzia gracilis*, *heliotrope*, *pelargoniums*, scarlet *geraniums*, *fuchsias*, *genistas*, *calceolarias* and scented *petunias*, and *gazania splendens*.

With early bulbs, in these window gardens, I have not had such marked success. Although they are in fair bloom now, they are little better or earlier than those in my garden below, and by no means show the same superiority as the *geraniums* and summer plants. This I attribute to their exposed and unprotected position during the winter, high in the air, and thus perhaps the same quality and airy situation which favours the later plants, acts adversely to the early ones. The window-garden, indeed, is attacked directly by frost below, in front, and at the sides, as well as at the surface of the contained earth; and this year, with its alternations, has been a trying one. Next year, however, I mean to try matting closely these window-gardens below, and round the sides, the matting lapping over the top, so that on fine days it may be easily opened from the windows, to let in the air and sun to the plants, and I hope by this means that while I retain the advantage of their high and airy position for the bulbs, on the other hand I may shield them from the alternations of frost.

It were easy, of course, to have the bulbs forwarded in a conservatory in pots, and then that they should be plunged in the earth of the window garden when the winter is over, but my aim has been to treat these receptacles legitimately as affording miniature gardens in all respects, without, however, of course, any prejudice to their being used in other ways as merely the receptacles of pots, as might be preferred by others.

There would be no excuse for my attempting to enter in detail on other branches of raising plants and flowers beside those of which I have had individual, and perhaps novel experience. As regards, however, other facilities for city gardening for indoors as well as out, I cannot well treat the subject without allusion to them. Excellent information on these matters is to be found in two little books by Miss Maling, entitled "Indoor plants, and how to grow them," and "Flowers and foliage for indoor plant cases;" also in a manual on window-gardening by Mr. Robert Fish; and on the table you will see these illustrated by the various appliances arranged there.

All the devices and graceful arrangements, of which these are samples, are evidences of the increase of the love of flowers in the population generally, and the desire of improvements in accommodating them, and fostering their growth either within or directly attached to houses; and when in London we walk abroad, we see proofs as marked in the great improvements of our public parks in this respect, not only in the more courtly quarters of St. James's, Regent's park, Hyde-park, and Kensington-gardens, where we are so much indebted to Lord Llanover, Lord John Manners, the late Mr. Fitzroy, and Mr. Cowper, the present first commissioner, but they are equally visible in

Battersea, and also in Victoria Park, where Mr. Preston, aided by various gentlemen, is forward in the development of the same taste. Nowhere, however, can a better display be seen than at the Crystal Palace, where the genius of Sir Joseph Paxton has so well combined art and nature. In another direction from this great city, it is a delight to see its inhabitants enjoying the varied sources of interest and information in the Royal Gardens at Kew, so much improved and improving under the scientific and refined taste of Sir William and Dr. Hooker; and beside these are the Horticultural Gardens at Kensington and Chiswick, and the Royal Botanic Gardens in Regent's-park. But we need not travel so far a-field, at least, for an autumn show of flowers. Nothing can illustrate the prevalence of the love of flowers more than its penetration into the very citadel and temple of law itself. Not far from here, and in the heart of town, as you all know, is to be seen yearly a beautiful show of flowers in the Temple Gardens, chiefly *chrysanthemums*, under the management of Messrs. Broome and Dale, the Temple gardeners.

Moreover, the smoke of London is lessening. The Thames is to be purified, and we are to have a Thames embankment, vieing, we trust, in beauty and magnificence with any river-side terraces in the world, and here we may well hope that our love for horticulture in connection with architecture, as indicated by Bacon, may find an adequate development, and the more the subject of the growth of flowers and plants in towns is winnowed, the better shall we be prepared to deal with it when it may come to us on this large scale. It has been suggested several times of late that this embankment and these terraces should be decorated by art; so be it, but let Nature come in as well to add her decorations, and the study of what plants and what flowers thrive best in cities, and under what treatment and at what elevations, is surely appropriate, when we have in prospect such a scope for the culture of flowers on a large scale, as well as the planting and cultivation of such trees as best thrive in London—as the plane-tree, of which Lord Llanover had so many planted about London—a boon to future generations.

Just now I mentioned elevation as favourable to the growth of flowers and plants in public places in cities, and I will now offer a few concluding remarks as to the same situation in smaller areas as regards domestic gardening. Window gardening is most valuable, evidently, where there is no other space for the purpose, and as affording to almost every one who has a window the opportunity of horticulture on a limited scale. But in many localities, even without going far into the suburbs, there are small garden plots attached to the houses, and in alluding to them as part of my subject I cannot do better than follow Miss Maling's observations quoted above, in which mention is made of the great advantage which arose in her experience from giving elevation to the situation of the plants. I have already mentioned what occurred in the Horticultural Gardens from an elevation of only four feet, and I found the same advantage in my own, which is contracted and hedged round with walls and lime-trees. Here, also, I placed an iron receptacle the same height against the wall on one side, in which I found *mignonette* grow much more freely than in the borders near, and a *genista*, especially, increased five-fold in the course of the season, during which it flowered continuously. This led me to the idea of a general raising of all the beds of a small contracted garden, so as to afford them a freer circulation of air and more sun. No doubt this is in some degree expensive, but in a small garden would be no great matter, and, I believe, would ensure the growth of plants and flowers in situations where they would not thrive at the usual level, for every foot of elevation gives an improved stratum of atmosphere. It is evident that something of this treatment is seen in the planting and growth of flowers in large vases, and on trunks of trees sawn into blocks, and on rockwork; but in these cases not at all the same amount of earth or equality of drainage is pro-

vided for. In deep-rooted plants this plan would not be efficacious, probably, as they would hardly change their habits to suit this mode of culture; but for most plants and flowers, such as are usually sown or bedded out in parterres, nine inches, or at most a foot, in depth of earth, with two inches of broken pots below for drainage, would be sufficient. The receptacles for these, whether of iron, terra-cotta, or masonry, would be nearly flat-bottomed and elevated on ornamental standards; and, having made some little sketches of the general effect, although too slight to be used as illustrations, I conceive that the elevation of all the parterres of a small garden in a regular pattern in this manner is capable of much elegance and convenience as well as advantage to the growth of the plants. It would probably be productive of some novel effects in appearance, and would be without precedent, but so much the better for that. I have spoken of its convenience, which would be particularly the case as regards lady visitors and lady gardeners. The crinolines would then find ample space to sweep under the parterres instead of over them, as they often do to the detriment of the flowers, in a small garden, where the walks were not originally laid out in contemplation of that remarkable personal embellishment. As regards stooping also, it does away with the necessity of this either for sowing, planting, tending, or examining the flowers, and evidently their bloom and fragrance are more directly available. Mignonette, for instance, when placed in the ground, you would hardly perceive the scent of in walking by, but raise it some three or four feet, and let it grow there, and it will welcome you with its fragrance whenever you go near. Thus will you be better repaid for your care, and the plant will be much obliged to you.

As it appears to me, this is a plan which might be well adopted in the suburbs, which the closer and loftier march of bricks and mortar is now invading in all directions, and the thus raising the parterres in this artificial manner a yard or so in elevation would be tantamount in effect upon the plants to removing them a mile or so into the country. I acknowledge that the building activity in my own neighbourhood gave rise to this idea in my mind, and although my little garden is by no means yet in the condition to require this general hoisting, yet I confess I hold it in reserve with some satisfaction for the possible time when I may think it expedient, for as far as I have tested the plan, I have found it to be attended with success.

This whole subject of the treatment of flowers and plants in and about great cities is one fertile of ideas, and it does not appear of small interest even in respect to London itself, when we ask ourselves the question, "Of its three millions of inhabitants how large or how small a proportion love flowers, more or less?" I believe the proportion is very large that delight in flowers, ranging from infancy to age. I conceive, indeed, that we may be as yet but on the threshold of the treatment of facilities for domestic household gardening in cities, and I have little doubt that a few years will see us much advanced in this respect. I am rejoiced, therefore, to bring this subject before you in this room, and to be sensible that the few remarks I have offered on it are the furthest possible removed from exhaustive, thus also giving the more room for the observations of others, which may probably be more practical as well as more suggestive than my own. I have indeed confined my remarks chiefly to my own little experiences, which have mostly been in the direction of such kinds of treatment as might be available to the artisan with his two or three windows, or the invalid with his one; in which cases a glimpse might be afforded as it were, of the country amid brick walls, lending a breath and sentiment of poetry to dwellings too apt to be prosaic.

Having thus returned to my starting point, "the growth of flowers and plants in cities," and the cheering adjunct it affords even to the insufficient dwellings of the poor, I cannot, perhaps, conclude my remarks more

appropriately than by the quotation of some charming lines by our nature-loving poet Cowper, which, although composed in the last century, are equally applicable in our great town now, and to the present subject. They occur at the end of the "Winter Evening." The poet says:—

"The love of Nature's works
Is an ingredient in the compound man,
Infused at the creation of the kind;
And though the Almighty Maker has throughout
Discriminated each from each, by strokes
And touches of His hand, with so much art
Diversified, that two were never found
Twins at all points—yet this obtains in all
That all discern a beauty in His works,
And all can taste them: minds that have been formed
And tutored with a relish more exact,
But none without some relish, none unmoved.
It is a flame that dies not even there
Where nothing feeds it. Neither business, crowds,
Nor habits of luxurious city life,
Whatever else they smother of true worth
In human bosoms, quench it or abate.
The villas, with which London stands begirt
Like a swarth Indian with his belt of beads,
Prove it. A breath of unadulterate air,
The glimpse of a green pasture, how they cheer
The citizen, and brace his languid frame!
Ev'n in the stifling bosom of the town
A garden in which nothing thrives has charms
That soothe the rich possessor; much consoled
That here and there some sprigs of mournful mint,
Of night-shade or valerian, grace the well
He cultivates. These serve him with a hint
That nature lives; that sight-refreshing green
Is still the livery she delights to wear,
Though sickly samples of the exuberant whole.
What are the casements lined with creeping herbs,
The prouder sashes fronted with a range
Of orange myrtle, or the fragrant weed
The Frenchman's darling? are they not all proofs
That man, immured in cities, still retains
His inborn unextinguishable thirst
For rural scenes, compensating his loss
By supplemental shifts, the best he may?
The most unfurnished with the means of life,
And they that never pass their brickwall bounds
To range the fields and treat their lungs with air,
Yet feel the burning instinct: overhead
Suspend their crazy boxes planted thick
And watered duly. There the pitcher stands,
A fragment, and the spoutless teapot there
Sad witnesses how close-pent man regrets
The country, with what ardour he contrives
A peep at nature when he can no more."

DISCUSSION.

MR. VARLEY made some observations upon early methods of domestic floriculture which had come under his notice, and pointed out how the growth of conservæ and other water plants converted hard water from a well into soft water, suitable for watering plants.

MR. PHILIP PALMER said the subject which Mr. Bell had introduced was one of great interest and importance to all who, from necessity or inclination, resided in large towns. As one of that class he had for many years attempted to make up for the want of a garden by resorting to the plan recommended in the paper. Living as he did within a few hundred yards from the spot on which they were assembled, he had not even the advantages of Mr. Bell's suburban garden, but, nevertheless, his attempts at floriculture had been attended with very fair success. With regard to growing plants on the top of the house, he found that they were often killed by frost in the winter, and by the sun's heat in the summer. He might mention that,

perhaps, his most successful results had been obtained with currant trees, from which he had gathered crops on a small scale. He had also succeeded in growing some very creditable ferns, of which he had placed some specimens on the table. He stated these facts for the encouragement of others; if they failed in flowers they could fall back upon ferns, which were easily procured. He seldom visited a fresh spot in the country without bringing away some specimens; and his collection (which contained many foreign ferns as well as British) amounted to nearly 700 plants. He also called attention to a plant well suited for window-culture—the *Bryophyllum calycinum*, cultivated by his daughter within his residence. It was propagated from the leaf of the plant itself, and would grow to the height of three or more feet in a pan and glass shade. He should be happy to find that the results he had obtained led others to try the experiment.

Mr. J. BAILEY DEXTON could not allow the observations of the last speaker to pass without saying a word upon the growth of fruit trees under glass. From his own experience he found that these might be successfully cultivated in London and the suburbs. He believed currant bushes would grow very well indeed under glass on the roofs of the London houses, and he was quite sure peaches and nectarines would do so; he knew of no more interesting plant to cultivate under such circumstances than the peach, the bloom of which was very beautiful, and the fruit as it was developed still more interesting and agreeable. He had grown that plant in pots in his own garden, which was not a large one, and they succeeded very well, the trees having, in some instances, yielded as many as two score of peaches each. A more interesting subject than this, he said, could hardly be introduced to urban populations, and he congratulated Mr. Bell on the able and agreeable manner in which he had brought it before them.

Mr. G. F. WILSON, F.R.S., said two or three years ago an article appeared in one of the periodicals, entitled "Orchards in Cheapside," in which the writer recommended growing fruit trees on the roofs of houses in the heart of London. With regard to the growth of plants in rooms, he would mention that he saw a very successful instance of that plan in a monastery at Einsiedeln, in Switzerland, where, in a plain whitewashed apartment, roots of ivy were planted at the four corners, and as they grew were trained up the walls and over the ceiling, the effect of which was very beautiful indeed. With regard to the promotion of this pursuit amongst soldiers, he thought it deserved attention. The Emperor of the French gave the greatest encouragement in this respect to his army in the camp at Chalons; and when a regiment left the camp it was a regulation that the gardens they had cultivated should be broken up, so that the succeeding regiment had to start afresh with the cultivation of the plot allotted to them.

Mr. SOWERBY could confirm the statement made by Mr. Bell as to the beneficial effects of encouraging this branch of recreation among the working classes of towns. He had been a good deal concerned in workmen's flower shows, and could state that a marked improvement had taken place in the plants that were exhibited. In the first instance, the shows were very indifferent, but in two or three years a great improvement took place, not only in the variety of the specimens exhibited, but in the cultivation of the flowers. It was stated in the paper that the great drawbacks to the growth of plants in towns were high walls and confined spaces, where it was said the atmosphere was vitiated and was not favourable to the vitality of the plants. To obviate this, Mr. Bell had recommended that the flower-beds should be elevated considerably above the ground. Undoubtedly that was a good plan, and he apprehended it was to be adopted principally for the sake of getting more light and sunshine. He believed the greater luxuriance of plants in the country was not so much owing to the better state of the air as to the large amount of light and sunshine

which they obtained there. He would mention that one important element of success in house floriculture consisted in keeping the leaves of the plants free from the deposits of soot and dust to which they were subject in large towns. The leaves being the lungs of the plant, its vitality in a great measure depended upon perfect freedom of respiration, without which vegetable life could not be maintained any more than animal life.

Mr. SLACK said after forty years' experience as a "roof gardener" he believed he was approaching to something like success. He began by adding a dormer to the garret in which he slept during the summer months; he then added other dormers, till he had produced what was practically a glass roof. He wished the meeting to understand that he had not adopted that plan entirely with a view to floriculture, but an additional inducement was the opportunity it afforded of enjoying a pure atmosphere. Mr. Slack having described the method by which he had proceeded in converting his roof into a greenhouse, expressed his opinion that flowers and fruits might be grown to a very large extent on roofs throughout London. His own efforts, he said, had been chiefly devoted to the cultivation of the grape vine, in which he had proceeded by different stages and on a gradually increasing scale until he had succeeded in producing grapes which had astonished all who saw them. On one occasion he had gathered as many as fifty bunches of a size and quality that bore favourable comparison with those grown under circumstances commonly thought more congenial, namely, in the hot-houses of the wealthy. His success had been gradual, but by perseverance in his plans he had arrived at results which were highly interesting and satisfactory, proving as they did that the system was capable of being carried out on a large scale throughout the whole of London, very much to the delight of those who had a taste for such matters.

Mr. WENTWORTH SCOTT said it was a popular fallacy to imagine that the presence of plants and flowers in a sleeping apartment was unhealthy. It had been asserted that plants at night, when deprived of the influence of the sun's rays, gave out carbonic acid gas, but this was not the case. The fact was that plants, under such circumstances, gave out oxygen, but to a less extent than when exposed to daylight.

Mr. BROOME (of the Temple Gardens) expressed the pleasure with which he had listened to the excellent paper of Mr. Bell, who, he said, had shown himself a good gardener, in the various and clever expedients he had adopted for the gratification of his taste in these matters. There was one feature in this subject which he (Mr. Broome) thought specially important, that was encouraging floriculture among the working classes of large towns. He had himself had the satisfaction of assisting in the establishment of no fewer than twenty-four floricultural societies in various parts of London and the neighbourhood, and he had been much gratified by the good results that had ensued from them. These societies numbered from 100 to 120 members each, and exhibitions were held twice a year. The effects, in a moral and social point of view, were most remarkable; as it was shown that in proportion as a taste for floriculture prevailed among the working classes, their habits and morals became improved. Besides, the love of flowers was imparted to their families, the result of which, he thought, was to be found in the fact that amongst the hundreds of thousands of visitors to the Temple Gardens, including a vast number of children, he very seldom had occasion to complain of any act of spoliation or injury. The societies to which he had alluded gave rise to a friendly and generous rivalry amongst their members in the production of the best flowers, and occasionally some of the members gave short lectures on various matters of natural history to their brethren. Having witnessed the satisfactory results which had obtained among the working classes from the encouragement of a taste for flowers, he had lately gone a step lower in the social scale, and had

turned his attention to ragged schools. He had presented a large quantity of flower roots to one of these schools in Clerkenwell, and had been astonished to find how well they were grown, showing the evidences of careful culture. With respect to shrubs and plants in London he found that what most injuriously affected vegetation was draughts. In parts of the Temple-gardens, where there were keen draughts, the trees and flowers died off. He had experienced more mischief from those draughts than from the smoke of London. In addition to the plants mentioned by Mr. Bell, as suitable for urban cultivation, he might mention the rhododendron. Bulbous plants, too, would grow well if care were taken to plant them sufficiently early. Crocuses, hyacinths, &c., should be planted at the latter end of September, to ensure good blowing in early spring. From not having planted his crocuses sufficiently early last year, he was now almost entirely without those blooms. With regard to that great public favourite, the chrysanthemum, he would remark that there was scarcely a window or house top throughout the whole of London where that really beautiful plant might not, with a moderate amount of attention, be successfully grown.

The CHAIRMAN remarked that undoubtedly Mr. Broome's practice as well as his precepts led them all to feel that there were very few flowers that were more interesting to the denizens of cities and towns than the chrysanthemum. When they observed the wonderful variety in colour, and the extraordinary advance that had been made in the growth of that flower, it was not a matter of surprise that it had become so general a favourite in cities. They must all have felt that a visit to the Temple Gardens during the season of the chrysanthemums was a real gratification, as it was, in fact, almost the only bright spot in London during that gloomy period of the year. That flower was a great favourite with the lawyers; whether it had any peculiar charms for the legal mind he could not say, but it was remarkable that many members of that profession grew that flower in their small gardens in town, and took a special interest in watching its growth. An observation had been made, that very little reference had been made in the paper to fruit-trees. From the title this was hardly to be expected. The paper was intended to be chiefly devoted to floriculture, and he was sure the meeting would feel that this subject had furnished matter, under Mr. Bell's able treatment, for a very interesting paper. Undoubtedly the interest of flowers was equal to that of any branch of natural history. They appealed to the educated mind as well as to the artistic mind; but they appealed also to the humblest mind. The poor man experienced as much pleasure in the floral beauties developed in his small garden, or on his window-sill or house-top, as the rich man experienced in his large gardens and conservatories. Undoubtedly the influence of floriculture upon the human mind was most healthy, whether it was in the humble garden of the cottager, or in the spacious conservatory of the rich, wherever the mind could hold communion with flowers, their influence could not fail to be beneficial and elevating. They must have been struck in the exhibition that took place at the Agricultural Hall last year, by seeing how numerous were the small specimens of natural history exhibited, showing that the working men must have spent many leisure hours in the fields collecting them. But it was not by the healthy alone that the beneficial influence of flowers upon the mind was experienced. It was his lot frequently to visit the wards of an hospital, where he had seen the handful of fresh flowers brought to the bedside of the sick, and how cheering they were to the suffering patient. Again, in those afflictions which resulted in the loss of the mental faculties, they found that there was still a lingering love of the beauties of nature as presented in the form of flowers, even where scarcely any other interest remained. They could not over-estimate the healthy influence of the promotion of this taste, especially among the populations of

large towns, for when they looked at the courts and alleys in which a large portion of the working classes were cooped up, they could not but recognise how large a source of enjoyment was open to them in being able to produce at their windows some beautiful, though simple, specimens of country flowers. He had now to ask the meeting to authorise him in their name to thank Mr. Bell for his very interesting paper, on which he had evidently bestowed much labour, evidencing as it did the affectionate interest with which he regarded the subject of floriculture. He trusted none would leave the room without feeling they had spent a couple of very pleasant, and, he hoped, improving hours, in considering this very interesting topic.

The vote of thanks having been passed,

Mr. BELL, in acknowledging the kind reception given to his paper, said his own shortcomings had been in great measure supplied, and his incomplete remarks supplemented by what had passed during the discussion. He was very glad the idea he entertained of greenhouses on roofs had been actually carried into effect, and he thought the raising of the parterres would be equally successful when put into practice.

The following articles were exhibited in illustration of Mr. Bell's paper:—A case, invented by Miss Maling, for the growth of indoor plants; Wardian and Waltonian cases, contributed by Messrs. Barr and Sugden and Mr. Philip Palmer; vases and other ornamental receptacles for flowers, of Messrs. Minton's manufacture, contributed by Messrs. Goode; and from the Messrs. Copeland, contributed by the firm; similar receptacles ornamented with Messrs. Maw & Co.'s tiles, contributed by Messrs. W. B. Simpson and Son; a variety of receptacles for flowers, by the firm of Messrs. Hooper and Co.; also various contrivances in wire for orchids and other plants, by Mr. Holliday, of Notting-hill. Specimens of self-supporting iron window gardens, manufactured by the Coalbrookdale Company, were also shown.

The thanks of the Society are due to the various contributors.

Proceedings of Institutions.

NOTTINGHAM MECHANICS' INSTITUTION.—The twenty-seventh annual report, adopted at the general meeting of members, Jan. 30, 1865, says that the resources of the Institution have been augmented by a considerable addition of members, whilst the elementary classes are gradually attracting a large number of students. The number of works in the library is 6,921, and the number of issues during the year amounted to 33,583; 397 volumes have been purchased, 27 presented, and 44 vols. of periodicals bound—making a total of 450. Among the lectures delivered were "Chemistry of the Breakfast Table," by Dr. Gardner; "On Hood," by Mr. W. Rowton; "Modern Society," by Mr. Edmund Yates; "Thackeray's 'Vanity Fair,'" by Mr. George Dawson, M.A.; "How the English Language was formed," by Rev. A. J. D. D'Orsey, B.D. With regard to the classes, that for French has mustered an average attendance of thirty students, being an increase of two on the last year. The average attendance in the German class has been eleven. At the close of the session for 1863 4 several members of the chemistry class obtained prizes and testimonials from the Science and Art Department of the Committee of Council on Education. Dr. Wilson has reorganized the class, and the number of students is sixty-three. Dr. Wilson has also organized a class for the study of Animal and Human Physiology. This class, so far, is both popular and successful, being attended by forty-nine students. The discussion class has been discontinued. The chess class continues in the same flourishing state, numbering seventy-four members. The singing class progresses most satisfactorily, and musters between sixty and seventy pupils.

The number of ordinary members is 1,020; of honorary 122; and of life honorary 85, making a total of 1,227. The whole exterior of the building has been thoroughly repaired, at an expenditure of about £110. The Committee have under consideration plans for improving the Large Hall, by the erection of a gallery, to accommodate 330 persons. The estimated cost is about £550. Mr. R. B. Henson, who has very ably discharged the duties of Finance Secretary for ten years, retires from that office. The Committee and members heartily thank him for his services. He will be succeeded by Mr. John Thorpe, who has been a member of the Committee for some years. The Naturalists' Society have improved the Museum during the year, and some valuable specimens have been presented. About 6,000 visits have been paid to the Museum—4,000 by the public, and 2,000 by the members of the Mechanics' Institution. The receipts, in this department, including a balance of £27 19s. 5d., amount to £60 0s. 1d., and the payments to £56 3s. 7d., leaving a balance in hand of £3 16s. 6d. The general balance-sheet of the Institution shows that the receipts amounted to £792, and that there is a balance in hand of £114 7s.

NATIONAL MEMORIAL OF THE PRINCE CONSORT.

The following is an abstract of the receipts and expenditure of the Central Executive Committee, appointed at a meeting held at the house of the Society of Arts, to promote a national memorial to the Prince Consort:—

To cash received—		
Subscriptions from her Majesty's privy purse	£550	0 0
„ the Colonies	6,912	19 7
„ Great Britain.....	7,142	4 11
Interest on investments.....	504	11 4
	£15,109	15 10
By purchase of Consols, &c.....		
By brokerage	£13,128	4 4
By advertising	8	7 0
By printing.....	789	5 0
By salaries	615	13 11
By postage	284	11 6
By sundries.....	232	11 0
	18	17 3
	£15,072	10 0
By balance of cash in hand.....	37	5 10
	£15,109	15 10

Approved at a meeting of the central executive committee, the 18th day of March, 1865. Ordered that the balance in the hands of the treasurers be paid to the credit of the trustees, appointed by her Majesty, viz.:—Viscount Torrington, Colonel the Hon. Sir Charles Phipps, K.C.B., and Sir Alexander Spearman, Baronet; into whose names the above-mentioned stock has been transferred.

FREDERICK BYNG, Chairman.

PORTUGUESE INTERNATIONAL EXHIBITION.

The programme and regulations for the International Exhibition (already noticed in the *Journal*) have now been published. The directors of the Oporto Crystal Palace Company and the Exhibition Committee have fixed Monday, the 21st of August, 1865, as the opening day. Every article produced or obtained by human industry in all countries will be admitted to the Exhibition, and classified under one of the four following great divisions:—1st. Raw materials and their immediate transformations; 2nd, Machinery; 3rd. Manufactures; 4th. Fine Arts. These four divisions comprehend 45 classes, a classification similar to that employed in former international exhibitions. Photography is included in the 4th

division. The general exhibition will occupy the principal nave and aisles of the Oporto Crystal Palace. For the fine art department suitable picture galleries are provided in the body of the building. The machinery will be placed in the annexe—a temporary iron building. The space available for exhibition, and exclusive of offices of all kinds, is in the nave, galleries, and aisles of the main building, about 47,400 square feet; in the principal or machinery annexe, 30,000 feet; and in the smaller rectangular annexe, 9,250 feet. No rent will be charged to exhibitors during the time appointed for the exhibition. Rough counters and wall space will be provided gratuitously. All goods and articles for the Exhibition must be delivered at the building free of any charge to the company, and at the risk of the exhibitor, the reception of them commencing on Monday, the 15th of May next, and none will be received after the 31st of July. The most effectual means will be taken, in combination with the civil authorities, to guard against fire and protect the property of the exhibitors; but the committee cannot be responsible for losses by fire or robbery, accident, or damage of any kind. The usual regulations as to the non-admission of organic substances liable to decomposition, and of phosphorus, gunpowder, and all detonating substances, have been made. Spirits or alcohol, acids, corrosive salts, and substances of a highly inflammable nature, will only be admitted by special written permission, and must be held in well-secured glass vessels, containing not more of any of those liquid substances than half an imperial pint each; and these are to be placed in trays of lead or gutta percha, large enough to hold the contents of the glass vessels should a breakage occur. Substances liable to give an offensive smell must be properly enclosed in air-tight cases; also all substances liable to melt.

All articles exhibited will be classified without regard to nationality; but in each class the objects exhibited by one nation may be placed together. Any exhibitor whose goods can properly be placed together will be at liberty to arrange such goods in his own way, provided his arrangement is compatible with the general scheme of the Exhibition, and the convenience of exhibitors. Prices of articles exhibited may be affixed in all the divisions. These prices are obligatory, under the penalty of immediate exclusion from competition, and loss of all prizes. Exhibitors cannot remove their goods, or substitute others for them, during the period of the Exhibition, without the permission of the committee. Exhibitors may employ assistants under the usual regulations. Free admission, within certain limits, will be given to exhibitors. Steam and water power will be supplied gratuitously. Besides making arrangements for showing machinery in motion, and illustrating it by processes, the committee will reserve space (if early application is made) for the exhibition of such processes of manufacture as can be carried on without danger to the rest of the Exhibition.

All intending exhibitors must state whether they are the designers, inventors, manufacturers, importers, or producers of the articles they propose to exhibit.

Exhibitors must insure their own goods, should they desire this security.

In forwarding the goods the exhibitors will have to send with the same a memorandum in duplicate, stating the name and Christian name of exhibitor (or firm), the address, the number and weight of the packages, and the description of the articles with the price of each. On application by exhibitors, empty packing-cases will be warehoused up to the end of 1865 at a fixed scale of charges. Distinctive labels will be attached to such goods as are intended for sale, the price of which will be entered in a book, kept by an officer of the Company, through whom all sales are to be made.

No copies, drawings, or photographs of any of the works of art will be allowed to be taken without the previous consent of their respective owners. The empty

packing-cases of the fine arts class will be warehoused at the Committee's charge. No exhibitor in the fine arts class can obtain a prize, not being the author of the exhibited work. At the close of the exhibition a permanent gallery for pictures, &c., will be formed, and artists and others may leave their works on view.

In regard to foreign goods admitted to the exhibition, the exhibition building will be considered as a custom-house store, under convenient regulations proposed by the Government.

To make the exhibition more complete and attractive there will be held, from the 5th to the 13th October, an agricultural show of living animals and plants. This show will constitute—in relation to the International Exhibition—a supplementary and temporary class of the 1st division. This class will include cattle, horses, sheep, pigs, poultry, bees, silkworms, open-air plants, greenhouse plants, stove plants, fruits, and vegetables.

Medals and certificates of merit will be awarded in all the divisions and classes, according to the decision of a mixed international jury, partly appointed by the Council of the exhibition, and partly elected by foreign exhibitors. Each class will have an especial jury, except where several classes have a natural connection, and are slightly represented, then one jury may adjudicate on a group of several. The president of each jury will be appointed by the Grand Council; but vice-presidents and reporters in each class shall be elected by the members of the respective jury, as mentioned in a former number. Mr. P. L. Simmonds has been appointed London manager, from whom forms and all information may be obtained, at the house of the Society of Arts. Messrs. Ivens and Son, of Crutched Friars, are appointed shipping agents.

Fine Arts.

PARIS ANNUAL EXHIBITION OF FINE ARTS.—As the readers of the *Journal* are aware, the jury charged with the selection of the works for exhibition, and also with the distribution of the prizes, is elected by the whole body of artists who have received any kind of recompense at former exhibitions. The list of the artists selected for the jury of the present year shows that the recent reforms introduced by the Government in the system of fine art education are popular with the artists; the names that stand first on the jury for painting and drawing being those of the three professors of the new school of Fine Arts—Cabanel, Pils, and Gérôme. Of these M. Cabanel only is a member of the Academy of the Beaux Arts, which is directly opposed to the new governmental arrangements; of the other members of the jury, two or three are members of the Academy. M. Meissonier, who, with two other well-known artists, is elected as supplementary, is also of the Academy. It must be remembered, however, that these selections are also greatly influenced by personal feeling as well as by professional opinion. The important fact is that the juries thus elected by the whole body of honoured artists are not only with respect to painting, but in the other branches of the fine arts, perhaps as well selected as possible. All the works sent in for exhibition were received by the 20th of the present month, and the number is at least as large as it was last year. The coming exhibition may be expected to include between three and four thousand paintings and other works of art. There is one circumstance which tended to increase the number of applications this year, namely, the expectation that, in consequence of the great International Exhibition of Paris in 1867, there will be no fine art exhibition in 1866. The *salon* of the present year is expected to be beyond the average; an immense number of excellent works have been sent in, but, at the same time, there is no one work which has yet attracted the *on dits* of the artistic world of Paris. M.

Cabanel, the poetic painter of the Florentine Poet, of Venus, and other well-known works, has sent a portrait of the Emperor; and M. Gérôme, instead of a Caesar or a Phryne, contributes a Reception of the Siamese Ambassadors by the Emperor. The exhibition opens, as usual, on the 1st of May.

MONUMENT TO CLAUDE LORRAIN.—The King of Bavaria has ordered a statue of the great painter to be placed, at his own special cost, on an elevation in the environs of Munich. The formal inauguration of the work is to take place in the month of May.

Manufactures.

INDUSTRIAL EXHIBITIONS.—An act of parliament received the royal assent on Monday last for the protection of inventions and designs at industrial exhibitions. The Board of Trade may certify "Industrial Exhibitions," and the exhibition of inventions and designs at such places is not to prejudice patent rights or registration.

THE DUBLIN INTERNATIONAL EXHIBITION.—On Monday last an act of parliament received the royal assent for the protection of inventions and designs at the Dublin Exhibition, to be held during the present year.

CORN SUGAR.—The *Buffalo* (United States) *Commercial* states that the parties interested in the recent discovery of sugar to be manufactured from corn are actively engaged in making preparations for the extensive manufacture of sugar by the new method, and that they will shortly be prepared to put the new staple upon the market.

ANCIENT PAPER.—The *Reader* says that Mr. Toulmin Smith, in examining a mass of rolls at the Record Office, dated 1388, made the discovery that linen paper was thus early used in England. The quality is peculiar, and is apparently an imitation of the texture of vellum. Mr. Smith, who has carefully examined the paper under the microscope, believes that he has found out the secret of its manufacture. It is as durable as vellum, and after five hundred years of very bad treatment, it has proved itself to be equally valuable for the preservation of public records. This discovery raises the question as to the date of the first paper manufactured in England.

IRON AND STEEL EXPORTS.—It is a remarkable fact that while our exports of iron and wrought steel amounted to 1,494,630 tons last year, as compared with 1,640,949 tons in 1863, the value of last year's exports was £13,214,294, against £13,160,936 in 1863. It cannot be said that any material advance has been made in our exports since 1857. This is to be attributed to the stationary and, in fact, diminished demand for railway iron, in consequence of the progress now made with the great Indian lines and the substitution, in part, of Belgian for English railway iron in Spain.

Commerce.

THE HERRING FISHERY.—An account of the Dutch fishery in 1863 appears in the "*Annales du Commerce Extérieur*," published by the French Government. The herring fishery of Holland, as regards the salt and dried fish trade, is falling off, the number of boats having diminished from 97 in 1859 to 86 in 1863. The exportation of herrings in barrels amounted to 35,089 tons, of which 21,000 were sent to Germany, more than 5,000 to Belgium, 1,450 to Russia, 3,891 to Hanover, Bremen, and the other free cities, 709 to the Scandinavian states, and 2,219 tons to the United States. The above total included, however, 16,693 tons imported, of which 15,993 tons were from Great Britain. Fishing for the fresh herring trade occupied 179 boats, which delivered in the market more than 38½ millions of fish, valued at nearly £40,000, the average price being about 18s. 4d. per 1,000.

The general decline in the sea fish trade of Holland is attributed to the ardent rivalry of the Scotch fisheries. Belgium is the largest customer to Holland; in 1863 she is reported to have purchased 30 millions of salted herrings, and 1,362 tons of fresh sea fish.

TRADE WITH MEXICO.—The exports of coal to Mexico amounted in 1859 to 3,111 tons; in 1860 to 1,965 tons; in 1861 to 4,566 tons; in 1862 to 12,776 tons; and in 1863 to 8,412 tons. The exports of wrought and unwrought iron to that country experienced great expansion, in 1863 having amounted to 8,868 tons, against 695 tons in 1862, 721 tons in 1861, 887 tons in 1860, and 271 tons in 1859. The value of the steam engines exported to Mexico in 1863 was £795, against £2,072 in 1862, and £58 in 1861. The value of other machinery, sent in the same direction in 1863, was £15,406, against £8,164 in 1862, and £7,308 in 1861.

IMPORTATION OF IRON ORE INTO ENGLAND.—An important fact, says the *Journal de Rouen*, which it is well to note, is the importation into England of iron ore from the port of Cherbourg, and brought from mines in the vicinity of that port. It appears that an annual supply of 18,000 tons has been contracted for between the proprietors of the mines and certain ironmasters of Swansea.

ARTIFICIAL FECUNDATION OF CEREALS.—The Minister of the French Imperial household issued a commission some time since to examine into the system of cultivation and artificial fecundation recommended by M. Daniel Hooftbreuk. The method of effecting the latter object was by means of a line, to which a deep fringe of woollen or other material was attached; this was drawn along the heads of the wheat or other grain, at the moment when the pollen was ripe, and it was supposed, would facilitate its diffusion and adhesion. The first portion only of the report has been presented, which announces that the experiments made on the imperial farm and in other places have not produced the promised results.

Colonies.

REVENUE OF VICTORIA.—The returns for the year ending the 31st December are as follows:—The actual amount received into the Treasury during the twelve months amounted to £2,847,295 5s. 9d., which, as compared with the estimated revenue of £2,978,000, showed a deficiency on the year of £125,704 14s. 3d. The principal deficiencies have been in the income derived from public works, and in the territorial revenue. In the former it amounted to £63,824 13s. 3d., and in the latter to £84,067 16s. 1d. As compared with the previous year, however, the revenue for 1864 exhibits an increase of £129,413 18s. 2d. The financial condition of the colony, therefore, appears to be satisfactory, as it is more than probable that when the whole of the revenue for 1864 has been collected the Treasury estimate will be realised.

GOLD IN VICTORIA.—The total shipments of gold during the year 1864 were 1,686,549 ounces, the produce of this colony, and 234,913 ounces the produce of New Zealand. The annual decrease in the yield of gold is steadily maintained, being 77,487 ounces, or 5 per cent., exactly the same rate as in the previous year. The intelligence from the gold fields is satisfactory.

SOUTH AUSTRALIAN STATISTICS.—The population of this colony is now about 160,000 persons; the total value of the imports, during 1864, was £2,412,931; and the total value of the exports, £3,305,545. The public revenue during the same year amounted to £766,635 16s. 10d., and the expenditure to £612,078 8s. 7d., there being in the hands of the treasurer, on the 31st December, a total balance of nearly a quarter of a million. The receipts from customs, as well as from land sales, showed a large increase, and the revenue generally was in a most flourishing condition.

LAND IN SOUTH AUSTRALIA.—The sales of Crown lands by public auction and private contract, from the commencement of the year 1864 to December 22, were as follows:—

Public auction, 136,063 acres sold for	£178,981 15
Private contract, 89,511 " "	90,247 0
Total	225,574 " " £269,228 15

A comparative statement of the sales of Crown lands by public auction during the corresponding periods of the years 1859 to 1863 inclusive, shows the average of the five years was 109,099 acres, sold for £144,188. The increase in 1864 over 1863 is 31,984 acres, and in value £41,883.

SALMON IN VICTORIA appear to be progressing favourably, and the salmon fry in the River Badger are said to be in good health, and rapidly increasing in size. The news from the breeding ponds in New Norfolk, Tasmania, is favourable. The salmon and the trout have grown rapidly, and it is now believed that the fish are thoroughly acclimatised, and that the waters of Tasmania are almost as well suited to the breeding of the fish as their own native rivers.

COMMUNICATION WITH NORTH AUSTRALIA.—Mr. Duncan McIntyre, and a friend, with three blacks, succeeded in accomplishing the journey, overland, from the Darling to the Gulf of Carpentaria, and back. This successful passage confirms the discovery made by Burke, that there is a practicable road, not only for men and horses, but for stock, right across the centre of the continent, and there can now be no doubt that nearly the whole of the interior of this vast island continent is habitable, and fit for the use of man. Even the stony desert of Sturt, so long a terror to bushmen, and a puzzle to geographers, is now shown to be for the most part a splendid sheep country. Northward of that, to the coast range, Mr. McIntyre found beautiful rolling downs, well watered and timbered. A permanent water supply exists throughout the entire route.

RAILWAYS IN NEW SOUTH WALES.—The last of the contracts on the Southern Extension, which will carry the railway into the town of Gleuburn, has been taken. The line will be twenty-six and a-half miles in length, and will comprise some very heavy works. Trial surveys have been taken of the country between Moama and Deniliquin. It is intended by the Government shortly to sell some of the land in that district, and it is also in contemplation to form a railway line in continuation of that from Melbourne to Echuca. In the event of the railways of this colony being connected with those of Victoria, a difficulty will be presented by the difference of gauge—the English gauge of 4 ft. 8½ in. being adopted on the railways in this colony, and the Irish gauge of 5 ft. 3 in. being adopted on the Victorian lines.

Obituary.

CONSTANT TROYON, the well-known painter of animals and landscapes, died on the 20th March. He was born at Sèvres, in the year 1810, and passed a portion of his youth in the Imperial China Works there, in painting on porcelain; but a few years of study under Riocreux, and several excursions into various parts of France, made him change his course to that in which he gained such a well-deserved reputation. He commenced exhibiting in 1833. Amongst his earliest pictures are a "Fête at Sèvres" and a "Corner of the Park of Saint Cloud;" but it was not till 1841 that a "View in Brittany" brought him into public notice. From this time he continued to gather all the laurels that the fine-art authorities of Paris had to bestow. He took the first-class medal at the public exhibitions three times, if not more, and was finally decorated with the Cross of the Legion of Honour. The number of his works must be very considerable, for he was

an indefatigable labourer. He represented nature animate and inanimate, in all her forms, and he united in a very unusual degree the powers of both a landscape and animal painter. One or more of his works are to be seen in the gallery of the Luxembourg, but perhaps his most remarkable production is a picture, exhibited four or five years since in Paris, representing a flock of sheep being driven to market in the early morning. At one time he was threatened with blindness, and a few months since a worse calamity overtook him, and he was confined in a maison de santé. He recovered his reason, but not his health, and he owed the few comforts of his latter days to a more fortunate brother artist, who enabled Troyon's mother to soothe the last few months of the painter's life in their own home. There is no French painter known who can take up Troyon's palette. His style was essentially different from that of Rosa Bonheur and her brother, and his landscapes exhibited that intimacy with and fidelity to nature which is not at all common with French artists.

KARL KISS, the sculptor, so well known by his "Amazon" in the Exhibition of 1851, was found dead in his bed at his residence at Berlin on Friday, the 24th of March. He had suffered for some time from congestion of blood to the head, and had been long resident at Karlsbad for the benefit of the medicinal waters. The deceased professor, who was a Silesian by birth, was a member of the Berlin Academy of Arts.

Notes.

INSTITUTION OF NAVAL ARCHITECTS.—The ordinary meetings for 1865 will be held in the great room of the Society of Arts, on Thursday morning next, at 12, and evening at 7 o'clock; Friday morning at 12, and evening at 7 o'clock; and on Saturday morning at 12.

THE COLOGNE EXHIBITION of the agricultural products of all nations stands adjourned to the 2nd of June, and will remain open from that date till the same day of the following month. The avowed object of the adjournment is to give English and French exhibitors the benefit of the new commercial treaty.

INDUSTRIAL EXHIBITION.—The Society for Improving the Condition of the Labouring Classes have organised an industrial exhibition of the production of the inhabitants of model houses, which will be opened on Tuesday, April 4, at the lower room, St. Martin's Hall, Long-acre, at two o'clock, when the Earl of Shaftesbury, K.G., &c., will preside.

AGRICULTURAL MEETINGS.—Between this and June the following agricultural societies will hold meetings:—On the 3rd April, the Botley Agricultural Society, at Botley. On the 17th, the Royal Dublin Society holds its spring meeting at Dublin, lasting four days. On the 1st, the Wharfedale Agricultural Society, at Otley. The Yorkshire Agricultural Society, at Ayr, May 15. On the 16th May, the Stettin International Agricultural Exhibition, lasting till the 21st. On the 25th, the Royal Cornwall Agricultural Society, at Falmouth, for four days. June 3, the Royal Hungarian Agricultural Show, at Pesth, closing on the 7th. June 6, the Bath and West of England Agricultural Society's meeting, at Glastonbury, for four days. On the 6th, the Essex Agricultural Society's meeting, at Brentwood. On the 6th, the Hampshire Royal Agricultural Society, at the Cattle Fair, at Basing. On the 14th, the Oxford and Banbury Agricultural Society's meeting, at Oxford. On the 16th, the Norfolk Agricultural Society's meeting, at Norwich; and on the 30th June, the Bedford Agricultural Society's meeting, at Bedford.

Correspondence.

PRESERVATION OF FOOD.—SIR,—In the question of South American beef, be it understood that *charqui*, or

jerked beef, is one thing, *tasajo*, or salted beef, is another. *Charqui* is muscular fibre, without fat, cut into thin flakes or strips, and dried rapidly by sun heat—i.e., the watery portion expelled by a hot and dry atmosphere, when it attains to the condition of glue, and will, if kept dry, last for a long period, though mites may be engendered in it like cheese. It does not lose its flavour in the process, and the mode of cooking is not by soaking, but by heating over the fire and pounding to shreds in a mortar to the condition of sausage-meat, and mixing with oil, onions, pepper, or other seasoning matter. *A fortiori* it will make nourishing soup, and there is no loss of nutriment by chemical change, as in salting. *Tasajo* is "another guess" kind of thing, prepared in climates where the air is not dry enough to take up the moisture of the flesh. So in Buenos Ayres and Monte Video fat and lean are cut into thin flakes, dipped in brine, and partially dried. This is sent to Brazil and the West Indies as a relish for the vegetable food of negroes, much like salt herrings, and the salter the better. But if this material be kept long the fat decomposes and becomes rancid. The muscular fibre loses most of its power of nutrition, and the fat becomes absolutely loathsome, save possibly to a Russian, who, it is said, prefers a rancid tallow candle to a fresh one, as an article of food. Hearing so much of South American beef lately imported as a cheap article of food, and remembering my old friend *charqui*, I was induced to procure some, and gave directions for cooking it in the best method, with no lack of appetising ingredients and flavours. But it was a material that not even a French cook could have dealt with to any purpose. The villanous substance was *tasajo*, rancid beyond my conception of any foregoing rancidity; to paraphrase Lachimo:—

"Base and (in)nutrient as the smoky light
That's fed with stinking tallow."

It was worse than the graves that hounds are fed on; worse than oil cake that fattens bad beef. It filled the house with its wretched odour, and made my friends sick. Even the dog looked suspiciously at it as something not canny. The only method of dealing with it would have been to treat it with caustic alkali, converting the fat into soap, and leaving the salted fibre free for mixture with *assafoetida*, garlic, onions, shallots, or other similar matters. There has been an ingenious suggestion that it would be admirable food wherewith to feed convicts in prison. I think that if anything would deter them from crime it would be the dread of such feeding. Skilligolee would certainly be at a premium in the prison dietary compared with it. Horsebeans are doubtless a very nourishing food, and horsebeans with fresh tallow would be a delicacy compared with rancid *tasajo*. There are people who are said to like it, but possibly it was not rancid in their case. But let it be understood that the fresh *charqui*, manufactured from the mountain cattle of Chile, of fibre and not fat, is quite a distinct thing from the salted *tasajo* of La Plata, with its rancid fat, produced on marshy plains, as different as Welsh and Lincolnshire mutton from each other. And the dry unsalted flesh would, as a nutriment, be cheaper at sixpence per pound than the moist salted at threepence. There may be nutriment remaining in the latter, but it would be necessary for the chemist to separate the noxious elements.—I am, &c.,

W. BRIDGES ADAMS.

MEETINGS FOR THE ENSUING WEEK.

Mon. ... Entomological, 7.
British Architects, 8.
Medical, 8.
Astatic, 8.
Geologists' Association, 7. 1. Mr. W. H. Leighton, "On the Geology of the Isle of Wight." 2. Mr. A. Bolt, "On the Neanderthal Skull."
Society of Engineers, 7. Mr. Zerah Colburn, "On certain Methods of Treating Cast-Iron in the Foundry."
Odontological Society, 8.
Royal Inst., 2. General Monthly Meeting.

- Tues.**...Society of Arts, 8. Cantor Lectures. Dr. F. Crace Calvert, "On some of the Most Important Chemical Discoveries made within the last two years." (Lecture I.)
Civil Engineers, 8. Discussion upon "Drainage of Paris" and "Metropolitan System of Drainage."
Pathological, 8.
Anthropological, 8.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

APRIL 12.—Passion Week. No MEETING.

APRIL 19.—"On the Preservation of Natural History Specimens for Museum Purposes." By B. WATERHOUSE HAWKINS, Esq., F.G.S.

CANTOR LECTURES.

There will be No LECTURE on Tuesday evening next.

Proceedings of the Society.

CANTOR LECTURES.

The first lecture of Dr. Grace Calvert's Course was delivered on Tuesday evening, the 4th of April. During the vacation the complete course of lectures, corrected and amplified by the author, will be published in the *Journal*.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 5, 1865; Edward Holland, Esq., M.P., in the chair.

The following candidates were proposed for election as members of the Society:—

Byrne, Geo. S., R.N., Royal Hospital, Greenwich, S.E.
Brackenbury, Capt. C. B., R.A., 1 Adelaide-place, Woolwich-common, S.E.

Brady, Francis, 12, Limes-villas, Lewisham, S.E.

Bumlen, Charles, 6, St. John's-road, Brixton, S.

Bart, C. J. T., Roadside, West Hill, Putney, S.W.

Clark, Edward, 2, Rose-villas, Montpelier-road, Peckham-rye, S.E.

Dotterill, W., Norbiton-park, Kingston-on-Thames, S.W.

Danby, Thomas, 7, Parliament-street, S.W., and 31, South-grove, Peckham, S.E.

Dolan, H., Park-hill, Clapham, S.

Elen, Frederick Morton, Chapel-house, Kew, W.

Farnall, Harry Barrard, Poor Law Board, Whitehall, S.W.

Field, Hamilton. Clapham-park, S.

Folkard, Augustus, Haslam-house, Lewisham, S.E.

Gibson, John, 1, Era-place, Surrey-lane, Battersea, S.W.

Goodwin, Rev. Thomas, M.A., Croom's-hill, Greenwich, S.E.

Gowan, George D'Olier, Wood-lawn, Dulwich, S.E.

Graham, John, 74, Manor-street, Clapham, S.

Harker, George, Uplands, Sydenham, S.E.

Harrison, C. Wrightman, Pneumatic Loom Company, 26, Lombard-street, E.C.

Hawley, Henry J., 4, Foxgrove-road, Beckenham, S.E.

Herapath, John, Catford-bridge, Lewisham, S.E.

Hills, F. C., Denmark-hill, S.

Hoblyn, Thos. Hallam, Rickling, Bishop's Stortford.

Holloway, William, 4, Park-road-villas, Battersea, S.W.

Hosegood, Thomas W., Rosendale-villas, West Dulwich, S.

Jerram, E. J., 3, Cedars-road, Clapham-common, S.

Johnson, John G., Assay-office, 18a, Basinghall-st., E.C.

Legg, George, 61, King William-street, E.C.

Lewis, Thos., Somerset-lodge, 35, London-rd., Croydon, S

Lord, W. B., 37, Stockwell-park-road, Brixton, S.

Macandrews, J., Roehampton-lodge, Roehampton, S.W.

McArthur, W., 1, Gwydyr-houses, Brixton-rise, S.

Martley, W., 15, Cedars-road, Clapham-common, S.

Menge, Rev. J. P., Electrical-hall, Park-villas, Lower

Norwood, S.

Milnes, William S., 11, Devonshire-road, Greenwich, S.E.

Monk, J. C., 3, Manor-road, Wallington, S.

Moren, George, 38, Threadneedle-street, E.C.

Painter, Henry, 1, Arlington-villas, Loughborough-park,

Brixton, S.

Papengouth, Lieut. Oswald C., 12, Bloomsbury-sq., W.C.

Price, Charles J., Carlton-chambers, Regent-street, S.W.

Tefft, Benjamin F., LL.D., 31, Upper King-street, Hol-

born, W.C.

The following candidates were balloted for

and duly elected members of the Society:—

Booth, Captain John, 21, Kensington-crescent, W., and

Conservative Club, S.W.

Chatwood, Samuel, Lancashire Safe and Lock Works,

Bolton.

Good, Joseph Henry, 21, Upper Hamilton-terrace, N.W.

Mackenzie, James Joseph, Jennings' Hotel, Albemarle-

street, W.

Morris, William, Carmarthen.

Scully, George, 4 and 5, Agar-street, and 7, Adam-street

Strand, W.C.

The Paper read was—

THE FOOD OF ANIMALS.

By PROFESSOR JOHN COLEMAN.

The subject which I have undertaken to introduce this evening is one of great importance, not only to those im-

mediately interested, but to the public generally, as an economical method of feeding must influence the price of meat. The tendency of English agriculture is towards an increase of live stock, and therefore anything relating to their management should be interesting. Great progress has been made in the management of fattening animals during the last ten years. Practices have been established, founded on more correct knowledge of physiological principles. Contrast the present system of cooking food—of mixing a variety of substances natural and artificial, and the use of the pulper and chaff-cutter, with the ancient practice of allowing a beast to fill himself with sliced roots and hay *ad libitum*. Still, there is room for improvement. Farmers are too often satisfied to carry on their business as they have learnt it, without testing their practice by reason and science; and shut their ears, as it were, to the valuable advice from time to time advanced by scientific men. The subject is, moreover, peculiarly interesting after such a season as the past, which has been remarkable for the deficiency both of roots and hay—an unusual event—for we have frequently suffered in one or other of these important products; the weather which proved injurious to the one having favoured the other. Both being deficient, our prospects last autumn were gloomy indeed, and now that the trial is partially over, we may congratulate ourselves that we have got through the winter so well. The evil has not been unmixt with good. Necessity, the mother of invention, has led to shifts and plans, in carrying out which important experience has been gained, to bear fruit in a more economical management hereafter. And although I do not anticipate that in ordinary seasons cattle will be fed, as a rule, without roots, I am certain that a smaller proportion will be found sufficient; and, consequently, a considerable saving will be effected in this costly produce. The value of well-made straw as food has been over and over again insisted upon; yet it needed such a season as the last to carry conviction to the sceptical. In future we may hope that more straw and less hay will be cut up; less roots, and more corn and artificial food used. I propose to consider the subject under three heads:—

1. Natural food—such as root crops, hay, and straw.
2. Artificial foods—grain.
3. The best means of using these materials.

The animal body consists of three descriptions of material, skin and flesh, fatty matters, and the bony structure, made up of nitrogenized, non-nitrogenized, and mineral substances, all of which must be supplied in the food. Now Mr. Lawes has found that the ox, the sheep, and the pig are composed of different proportions of these substances, and that the proportions vary in the same animal, according as it is in store or fat condition; that, as the animal becomes ripe, the proportion of nitrogenous, mineral matters, and water is reduced, whilst fat (non-nitrogenous substance) increases largely; thus the ox contains 18 per cent. of nitrogenous material in a store state, and only 15 per cent. when fat; 16 per cent. of non-nitrogenous compounds in the animal is increased to 30 per cent. when fat, whilst mineral matters recede from 5 to 4 per cent., and water from 60 to 51 per cent.

Most vegetables in a ripe state, and when grown under proper conditions, are composed, in differing proportions, of a flesh-forming material, a heat-producing substance, and some mineral matter, required for the bones and juices. A large proportion of all vegetables consists of starchy materials, or digestible fibre, whose use in the animal economy may be likened to the fuel which supports ordinary combustion; it is taken into the blood, and then slowly burned, producing heat, so necessary for the preservation of animal life. The amount of fuel required depends upon the description of animal, and the exposure to or protection from cold. If we have an excess of such material, it is partly accumulated as fat. A great distinction is however to be made between starch, sugar, and digestible fibre, and the vegetable oils, which are almost identical in composition with fat. Mr. Lawes concludes,

from his experiments, that starch, cane sugar, and probably digestible fibre, have, weight for weight, nearly equal feeding qualities, whilst fat and oil have probably about $2\frac{1}{2}$ times the value of those materials, for the purposes of respiration or storing up fat in the system.

ROOT CROPS.

The Swede.—According to Dr. Voelcker, the bulb contains about 88 per cent. of water and 12 per cent. of solid matter, consisting, in round numbers, of—

Flesh formers	2 parts
Sugar, gum, starch.....	$1\frac{1}{2}$ "
Vegetable fibre (digestible)	$5\frac{1}{2}$ "
Mineral matter	3 "

The mineral matter is of great importance, containing all those salts required in the tissues and bony system. Thus in the whole plant we find a large proportion of the ash to consist of potash, phosphate, and sulphate of lime, and common salt. It is calculated that a crop of twenty tons of swedes robs the soil of about 500 lbs. of mineral matter, which must be returned to the soil, either by sheep feeding or a direct application of manure. Turnips and hybrid varieties differ from the swedes only in containing more water and therefore less solid matter. It will be seen that the root crop is, for a given bulk, not particularly nutritious; the experience of the past season proves that it may be to a great extent replaced by other materials; and I do not hesitate to state that an unlimited supply of roots is often very injurious. The nutritive qualities of roots depend upon their condition; like all other vegetables, they pass through different stages of growth, and if consumed before being properly matured, or grown on soil that is not properly enriched, they are not only un-nutritious, but frequently prove injurious. Who has not remarked the severe losses in young sheep when first put on swedes in a growing season, and when the plants are in a very fresh state? This is due to the unripe condition of the crop, producing violent disturbance of the digestive system; in fact, just the same result as if we eat unripe fruit.

These unripe roots are found to be deficient in gum and sugar, and to have an excess of nitrogen. As a proof of the correctness of this view, it may be noticed that the locust bean, a food very rich in sugar, has been found to arrest this dangerous scour. Recent examination has proved that all food in an unripe and unhealthy state contains more nitrogen than when ripe, and now, the proportion of sugar, gum, &c., is a surer test of value. Some very important practical considerations arise from these facts. Root crops should not be consumed until they are fully ripe, and hence it follows that early-planted well-grown turnips will do for animals better, at a certain time, than swedes. Land that is undrained, or supplied with an excess of manure, will not mature its crops; and, lastly, swedes and mangolds will, as a rule, be greatly improved by storing for a few weeks, as the ripening process goes on rapidly in the heap, and there is a considerable increase of sugar and soluble materials. It will be remembered that there was a time, comparatively recent, when our scientific authorities believed that the nutritive value of food was dependent upon the proportion of nitrogen present. Now we know that an excess of nitrogen is a proof of an unhealthy condition, and that whilst a certain portion of flesh-forming material is highly important, it is the proportion of gum, sugar, starch, and digestible fibre that really determines the nutritive qualities. In wet, cloudy seasons, when there is an absence of direct rays of the sun, we must be especially careful how we consume our roots. The eating a large bulk of such raw material, unqualified by sugary or oily food, will prove most prejudicial. For all these reasons I recommend the storing of roots whilst they are in a comparatively growing state; the moderate use of farm-yard and other highly nitrogenous manures to the root-crop, and their complete mixture with the soil, where practicable, instead of the old plan of placing such

material immediately beneath, and in close contact with, the crop; and, above all, storing for a few weeks before using. There is, moreover, economy in this latter practice, as regards all crops to be consumed in the winter and spring, for if left exposed in the soil the proportion of woody matter continues to increase at the expense of the starch, &c.

Mangolds are a most valuable root in the southern and drier countries of England, but seem unsuitable for the moister climate of the north. The crop requires heat in order to mature. According to Dr. Voelcker, the mangold bulb consists of 86.04 water and 13.96 dry matter, which latter is made up of—Flesh-formers, 1.81; heat producers, 11.19; mineral matters, .96. As a general rule, the mangold is not fit to eat until it has been stored for some months, but this entirely depends upon the soil and the season. On porous, well-cultivated soils, the mangold crop last year was much more suitable for immediate use in November than the swedes, which were growing fast, whereas the mangold, in consequence of the hot, dry summer, had matured its sugar, and in many instances it was eaten on the ground, and the stock did remarkably well. After a wet autumn—on the contrary—the mangold would prove most unwholesome, and would, in all probability cause the animals to scour, and do them harm instead of good. This is generally the case, and as the root possesses excellent keeping properties, I advise storing and not beginning to consume until the end of February or March. So nutritious is a well-kept mangold that I have seen stock sows quite fat from eating this root. The use of salt as a manure for mangolds has been constantly recommended, though I know of no very conclusive experiments. The mangold is derived from a seaside plant, and its ashes contain a considerable proportion of salt, but the indiscriminate use of salt is very dangerous; on all strong soils it will do harm, as it retards growth, whereas on warm, quick sands and gravels, by checking growth, salt does good, as there is a tendency under such conditions to return to the original annual state, and we see many of the plants running to seed. Salt will probably check this, and four to five cwt. per acre sown broadcast will be likely to do good. No stock farmer should be without a few acres of mangolds, to be kept in reserve against a backward spring; they are then invaluable and are never in the way, for if we have abundance of grass, &c., a few cut up will make an agreeable change.

In our short notice we must not omit the *cabbage*, which on all rather strong, well-cultivated soils, is a most valuable crop. According to Dr. Voelcker, we have much less water in the outer leaves than in the inner leaves and heart; thus he found in outer leaves only 84 per cent., whilst the heart and under leaves contained 89 per cent.; the average proportion of gum sugar is about 7 per cent., and rather less than 1 per cent. of ash. The cabbage is found useful for all kinds of stock, and, whether for the production of milk or fat, is a valuable food. It is expensive to grow, and requires plenty of manure, but coming in during the summer and early autumn is of great use, as we are then often short of, or at any rate, want a change of food. It may also be grown as a winter crop, and stands frost well.

Rape is a crop that on peculiar soils—such as the peaty soils of Lincolnshire, the marls, and strong soils generally that contain lime—does well and affords much valuable keep. The soil should be well tilled and in a highly enriched condition—the climate rather moist and warm. From the large amount of nitrogen compounds and starchy matters (11½ per cent.) that the rape contains, we can readily understand that the nutritive qualities of the crop greatly depend upon favourable conditions, and such is the case. In a wet, cold season, or if eaten off at a wet time and whilst in a very growing state, rape proves an unhealthy food, causing scour; and I should recommend that sheep be gradually introduced to this succulent crop,

and never allowed to consume it without a good supply of dry food to act as a corrective.

Grass and Hay must not be omitted from our notice, as forming so considerable a portion of all natural produce. Hay made from good sweet land, consisting of a variety of grasses, is the best possible food we can use; and more milk, and possibly as much beef, will be made from an unlimited supply of good hay and water as by any other mode of feeding. But we cannot afford to use hay in this way; we must keep an increased stock, and we find that hay is often a very expensive food, inasmuch as laying up the land for it curtails the summer stock, and frequent mowing weakens the land. The feeding value of grass depends in a great degree upon the presence in the soil of those mineral substances which the better grasses require; a variety of different grasses and leguminous plants are then encouraged, which, from their various qualities, form a mixture highly suitable to the digestive process, and also are of regular and slow growth. I do not doubt that an examination of our best grazing land would exhibit a great variety of grasses, and I am quite certain that very rapid growth is undesirable. This, to some extent, is the reason why water meadows and sewage grass are comparatively so weak. The grass is forced too rapidly to become properly matured, and the excessive rankness of certain descriptions which rejoice in an excess of moisture, keeps in check other kinds of grasses, and hence the produce is more simple than that of natural upland grass. These facts, whilst they may not, under certain circumstances, militate against water meadows or sewage, point out that whilst animals are on such food, we should do well to supply artificial matters containing sugar or oily materials, to counteract the excessive quantity of nitrogen which such food invariably contains. Mr. Lawes' experiments at Rugby lead him to the same conclusion. One of the oxen fed there was considerably lighter after having his fill of sewage grass for many weeks, and all the animals did badly. But when 4 lbs. a day of linseed cake was added to the grass, the improvement was visible and satisfactory. Sewage grass is better adapted for milk cows than for any other descriptions of stock, but even with them it will not do well alone: it is too watery. I have seen ewes and lambs on the water meadows in early spring doing very badly with abundance of grass, especially if the weather has favoured a rank growth; and I cannot condemn too strongly the practice of thus feeding sheep without some dry and nutritious food. Undrained land, again, favours the growth of coarse watery grasses, which seldom can be properly matured. Hence the pasturage is always inferior, although the actual bulk of produce may in some instances be found to exceed that from the same land when drained. In most cases where rot in sheep, splenic apoplexy in cattle, and other diseases of the liver and digestive systems occur, the grass will be found unmaturing, and containing an excess of nitrogen.

Well-made hay from good dry pastures is without question very valuable food, and food that I strongly recommend, provided it is not too costly, which at the present day, with our resources, we believe it frequently proves. According to Dr. Voelcker, good meadow hay contains more oil, fatty matters, and sugar, but less flesh-forming materials than that from artificial grasses, and both are superior to straw. Hence the value of a portion of hay for young growing animals. But with the aid of artificial food, straw may be largely substituted for hay, both for feeding and growing stock. And this is one of the great improvements of feeding in modern times, well deserving of most serious attention. The nutritive value of straw depends upon the condition and nature of the soil and climate. Some land will produce much more nutritive straw than other land, depending upon the process of harvesting adopted and upon the description of straw, the last stages of ripening, or, more correctly, of over-ripening, consisting in the change of soluble to insoluble matters. You will see, by examining the table, that the total

amounts of different ingredients do not differ materially between the fairly ripe and the over-ripe straw, but the condition in which the ingredients exist is widely different.

COMPOSITION OF OAT STRAW, AND HAY.

	Oat Straw cut green.	Oat Straw fairly ripe.	Oat Straw over ripe.	Cliver Hay.	Meadow Hay.
Water	16.00	16.00	16.0	20.50	16.66

Total	1.25	.63	.56	2.20	1.29

10 per cent. of sugar has become reduced to 3, and other changes have taken place, principally in the proportion of soluble and insoluble woody fibre. It may be asked naturally, whether, by cutting our crops before they become fully ripe, the grain does not lose weight or bulk. I answer not, if cut at the proper time, which practical experience can alone decide. Wheat and oats are now cut in a much greener state than formerly, and it is found that the sample is brighter, contains less bran, and is quite as bulky, considering that there is little or no loss from shedding, and in the case of a wet season, greater power to resist the action of moisture. From the table, it is clear that the very green sample, cut some twenty days before the period of dead ripeness, contains matters that should have gone into the grain.* About ten days to a fortnight before dead ripeness is the best time to cut oats, when some of the bell has turned yellow, and the straw is partly turning. I have cut white oats so green, that when lying in swarth, they looked almost like grass, and I feared the sample would contain green corn, but it turned out a beautiful bright colour, weighing 45 lbs. per bushel. It is evident that, in the case of oats more especially, the grain feeds from the straw after it is cut. The materials remain in a soluble condition, and the straw is doubted in feeding value. The difference in value of different kinds of straw is so considerable as often to influence our choice of crops.

Pea and bean straws are both valuable, especially the former, which, when cut moderately green and harvested without wet, is often equal to poor hay, and will be eaten with great avidity by all kinds of stock. Beans contain more woody matter and require to be more fully ripe, therefore are less nutritious; still, the upper portions and the pods form excellent food, and I have seen ewes, especially during severe weather, kept in capital condition with bean straw and a minimum quantity of turnips. Oats come next in value, and every handful of such straw, when sweet, should be passed through the animal's body. The waste that we too often see from the straw being left unthatched is deplorable: the first rain soaks in and damages a large quantity of valuable food. It should be taken as much care of as hay. Barley straw is mechanically suitable for food, and does well to mix with harder materials; but, being generally cut dead-ripe, there is but little soluble matter, and I consider it as the least valuable of our straws. Wheat straw has been much used during the past season, and when cut green and mixed with oat straw it makes good chaff. Still, it is too harsh to be used in large quantities; we should expect irritation of the mucous membrane from too much

of such dry material. One great point gained by the use of straw in place of hay is the increase of spring and summer food—both on the pasture land and artificial grasses—and this is most important, as it enables us to keep a heavier stock during the summer, a great difficulty on many light-land farms. In Lincolnshire, so justly celebrated for its farming, they hardly make any hay at all, the seeds being folded off by ewes and lambs. The use of straw, chaff, and pulped roots, in place of long hay and sliced turnips, is one of the great improvements in modern agriculture.

Having thus briefly alluded to the natural produce, more especially grown for stock food, we pass on to consider the various materials extraneous to the farm, which are now brought within reach of the farmer. Whilst our corn produce keeps at the present low rates, it is decidedly a good economy to pass a considerable portion through the animal's body—make our produce walk to market, as the saying is. At the same time, in order to feed economically, we must add to such food other materials, because they contain ingredients which are of great use in feeding, and which our own grain is deficient in, and, moreover, experience has proved that a mixture of different materials is highly desirable.

Linseed Oil Cake has been employed to a far larger extent than any other artificial food, and has risen greatly in value; nor is this the only difficulty. The ignorance as to what a really pure cake should contain, the absence of all analytical tests, and the stimulus of keen competition, has led to the sale of vast quantities of rubbish, containing, with some linseed, a mixture of all sorts of weeds, some actually injurious, and all inferior in feeding qualities. Attention has been lately called to this subject. The farmer has been told, in the clearest language, what a good cake should contain, and by a payment of five shillings any member of the Royal Agricultural Society, if he fears his own judgment, can obtain an opinion as to the genuineness of the article. Many avail themselves of this privilege, but it must be confessed that there are difficulties in the way of obtaining a pure cake, for which the crushers are not altogether responsible. The seed seldom comes clean, and if the 10 to 15 per cent. of dirt and weeds is screened, the crusher must have an extra price for his cake, and this the farmer will seldom give; he is too fond of a cheap article, and looks at the saving of £1 to 80s. a ton, rather than to the actual value of the two samples. The manufacturers must supply the demand; they cannot control it, and if they find that for every ton of pure cake they can sell ten of ordinary kind, they will naturally make that article which pays them best. Many attempts have been made by crushers to supply a perfectly pure cake, but on the whole such attempts have not met with the encouragement they deserve. When seed is dear, a variety of foreign matters are introduced, in order that a cheap cake may be produced. Thus, ground earth nuts, palm nut kernel cake, from Hamburg, &c., have been introduced into Hull and other places. The difficulty of getting a really good cake has induced a company of farmers in Yorkshire to start a mill, and make their own cake from good screened seed. But it has not hitherto been found a very profitable arrangement. Good linseed cake, made from East Indian seed, should exhibit a red seed, and, upon analysis, should yield from 10 to 18 per cent. of oil, 28 per cent. of flesh-forming constituents, and not more than about 15 per cent. of insoluble woody fibre, with about 6 per cent. of mineral matters; the latter particularly rich in potash and phosphoric acid, which partly explains the high value of manure from animals eating oil cake. Foreign cake, especially such as was imported from New York before the war broke out, was preferred by many as being drier and freer from impurities; latterly, however, the samples have not been so good, whilst French and German oil cakes vary greatly, and are not, on the whole, to be depended upon. Linseed cake is an exceedingly valuable material, being

readily eaten by all descriptions of stock, and containing in good proportion the flesh-forming, the heat and fat-producing, and the bony food. The oil is not of the most fattening nature; indeed, in excess, its action is purgative, but when diluted with an equal quantity of meal from grain, this is not felt to be an objection; indeed, it may be perhaps advantageous, as it ensures a healthy condition of the bowels. The large proportion of flesh-forming matters renders linseed cake particularly suitable for young growing cattle. It is, however, a very costly article at the present time, and I think we may lay down a very general rule that whenever good linseed cake exceeds about £9 a ton we must consider how far we can find cheaper materials to take its place. Fortunately, linseed is not our only source of feeding vegetable oil. Of late years, large quantities of other materials, such as rape, cotton seed, and palm nut kernels, have been introduced, and have, in many instances, successfully taken the place of linseed cake.

Cotton seed cake has been and is used to a large extent. Before the American war New Orleans supplied us with a considerable amount, in a decorticated state, that is, free from the greater portion of its hard, indigestible shell. In this state cotton cake was a very valuable article, nearly, if not quite, equal to linseed cake. Now, the quality is very various, and the best contains so large a proportion of woody fibre, that I do not consider it so desirable as many other kinds of food. In selecting cotton cake, choose that which is finely ground, and yellow in colour; this is less indigestible than the black, coarse-ground cakes which we frequently meet with. Several instances of death from the use of bad cake might be quoted. The indigestible shell accumulates in the third stomach, causing inflammation. I think cotton cake unsuitable for young animals, both on account of the shell and the portions of cotton which are frequently found in it. The analysis of three samples, by Dr. Voelcker, gives an average of—

Moisture	11.34
Oil	6.18
Flesh-formers.....	23.72
Gum, sugar, &c.....	30.98
Woody fibre	21.24
Mineral matter	6.54

100.00

The large amount of ash, which, like linseed, is rich in potash and phosphoric acid, points out cotton cake as likely to influence the value of the manure, as we find that Mr. Lawes, in his theoretical comparison, places it at the head of the list. Samples of cotton cake, with from 25 to 40 per cent. of woody fibre, are occasionally met with. Such food must be highly indigestible. Fine grinding is a point of great importance. A good sample is now worth £5 10s. to £5 15s. a ton, and at such a price will be found economical for growing stock, not too young.

Rape Cake when pure is a valuable food, and deserves a more extensive use. English cake, made principally from East Indian seed, is inferior to German cake, since the cultivation is not so clean, and the seed is adulterated with wild mustard, charlock seed, &c., and, as all these seeds are of the same shape, it is impossible to separate them. Instances have occurred of animals having been poisoned in consequence of the large admixture of wild mustard, which acts as a violent irritant on the mucous coat of the stomach, producing inflammation. I do not mean to infer that good rape cake is not made in England, because clean seed is obtained from the Continent; but, as a rule, the green German rape cake is very superior, and commands usually £1 a ton more than English. The principal objection to rape cake is that its strong, pungent flavour is objected to by cattle, and patience and time are required in order to bring animals to take to it. New cake especially should be avoided, as it loses some of its pungency by age. Some recommend

boiling or steaming the rape, for an hour, which destroys the oil of mustard, should any exist, and renders even good cake more mild and palatable. I have known it thus treated and poured over chaff with success. Such a mixture would do well for straw yard cattle. The following anecdote shows how completely animals are, like ourselves, creatures of habit:—Some years since I was feeding two home-bred steers upon linseed cake and meal. In early life, and, indeed, until the fattening process commenced, they had received a small quantity of rape cake, which was replaced by oil cake, as they had become fat. The cowman one day gave them a piece of rape cake, and finding it eagerly consumed, introduced a little, and to his surprise found that they liked it decidedly better than the linseed, and accordingly they were finished off on rape cake. Their tastes had been cultivated to prefer the bitter, hot rape cake to the mild, pleasant linseed cake. So if we begin with young animals, we shall soon teach them to eat it. The best green German rape is worth £6 10s. to £7 a ton. Alderman Mechi is a most consistent advocate of rape, using, I believe, English cake; he believes it to be equally as feeding as linseed cake, at a greatly reduced price.

PALM NUT KERNEL MEAL.

This comparatively new feeding material is produced from the palm nut kernels, which are ground up, and a portion of the oil expressed; formerly this kernel, which is encased in a hard shell, was thrown away as valueless, the orange coloured flesh of the palm fruit being the portion from which alone the crude palm oil was obtained. It is now some five years since Messrs. A. M. Smith and Co., of Liverpool, were induced to try a few tons of kernels. The hard shell is removed by natives in Africa, who break it off with a hammer. The kernels vary in size from a hazel to a filbert. After being reduced to powder, they were treated very much the same as linseed; a valuable oil results, and the meal which remains still contains, according to quality, from 20 to 25 per cent. of a beautiful fatty matter. At first it was found difficult to find a market for the meal, and it is on record that some of the first made was thrown away. It was soon found that pigs grew fat on it, and a sample reached Dr. Voelcker, who found it contained materials that should make it a very valuable feeding substance; subsequent experience has fully confirmed the accuracy of this view.

Until the spring of last year the supply of kernels was too irregular to allow of a fair trial being made or the meal becoming generally known. Several farmers, however, used it with success. I myself was the first to try it, and, after a little trouble in accustoming the stock to eat it, found it so valuable that upwards of 30 tons were used in a little over two years. Last year arrangements were entered into to secure an abundant supply of kernels. The matter was then brought before the public, and so active has been the demand that Messrs. Smith have had as much as they could do to supply orders. Palm-nut meal is a gritty meal, of a brownish-white colour, with black specks, which are portions of the skin of the nut. The fatty matter may be seen by rubbing a portion between the fingers, and is evident to the taste, it having rather a nutty flavour. Besides containing from 20 to 25 per cent. of a very feeding oil, we have 15 per cent. of flesh-forming material—about equal to good barley meal—only 15 per cent. of woody fibre, and a considerable amount of ash. Altogether, then, analysis indicates a most valuable substance, which, when mixed with other materials, will prove an economical food, and this view has been fully confirmed by practical experience. It has been tried for cattle, sheep, and pigs. The effect on milk is remarkable, increasing the quantity and especially the richness of the produce without affecting the flavour of the butter. The dairymen in Leicestershire have used it very largely, and found it of the greatest service during last winter to help out the natural produce. For sheep it has also been successfully used. Indeed, it is useful for any stock, whether

growing or fattening, provided we mix with it other food. The only point requiring care is in getting stock to take it. Animals that are in high condition and have been accustomed to oil cake do not take to it so readily as poor stock, but a little patience and perseverance will soon overcome this difficulty, and when once accustomed they will eat it readily. Mr. Clarke, steward to Mr. Edward Holland, M.P., tells me that his short-horn heifers, which received the best oil cake through the summer, have done quite as well upon the same weight of palm-nut meal, and when we compare the prices of the two, £6 a ton for nut meal, and £11 to £12 for linseed cake, we can understand the value of this new feeding material. Messrs. A. M. Smith and Co., of Kent-street, Liverpool, are the only English makers. Palm-nut kernel cake and meal from Hamburg is an inferior article, since the oil is extracted by a different process, dissolved out, I believe, and a smaller per-centage, about half, remains in the cake. It is a harsh, dry material, very different in appearance and taste from the English meal.

The following table shows the composition of both :—

	English Palm Nut Meal.	Hamburg Cake.	Hamburg Meal.
Moisture	7.21	12.91	10.84
Fatty matters	22.79	9.48	12.49
*Albuminous compounds ...	15.56	18.25	14.06
Mineilage, gum, and digestible fibre.....	36.24	39.16	43.56
Woody fibre (cellulose) ...	14.90	16.90	15.82
Mineral matters	3.80	3.80	3.73
	100.00	100.00	100.00
*Containing nitrogen.....	2.49	2.87	2.25

I look upon palm-nut meal as the best substitute for linseed cake that has yet been offered to the public. Its large amount of ready-made fat supplies a most valuable material, of which our home-grown foods are all deficient. Its reasonable price renders it a decidedly cheap food, that will compare favourably with grain, even at its present low price; and, from an extensive experience, I recommend it to the agricultural public as a valuable feeding material.

The question of employing Indian-corn, lentils, &c., depends upon the comparative cost of such articles and barley, beans, and peas. At present prices it hardly answers to sell our own produce and purchase such food, as the difference in price, according to quality, is not enough to cover expenses of taking to market. Indeed, during this last winter, a considerable quantity of the coarser descriptions of wheat have been ground up, mixed with some fat-producing food, and used with good results as cattle food.

Locust Beans, which contain over 50 per cent. of sugar, have been from time to time advocated, but save as an ingredient of the various cattle foods, which are extensively advertised, they have not come into general use. The importation is limited. Ground into meal, the use of from 10 to 15 per cent. is to be recommended, as it gives a relish, and makes the animals eat less palatable food. The same amount of malt would possibly do as well.

Malt.—Mr. Lawes' experiments have shown that there is no advantage in using malt in place of barley, or, indeed, in mixing the two. A considerable loss occurs in the process of malting, besides the cost of the operation. On the other hand, we know that many of our most successful feeders have been in the habit of adding a small portion of malt to their other food, when they desire to feed an animal to an extreme point; and I think it is a question that is worth careful investigation as to whether the

addition of a small quantity of meal would or would not prove advantageous. Judging from the use of locust-beans, which, when given largely, destroy the animal's appetite, I should have concluded, independently of Mr. Lawes' experiments, that malt would not do if supplied in any quantity; too much sugar is objectionable.

A word as to *Cattle Condiments*.—If animals are out of health and require a tonic to stimulate digestion, then the addition to the ordinary food of some substance like fenugreek, aniseed, or caraways, in a small proportion, will be found useful, creating an appetite. If, again, we are fattening an animal to an extraordinary degree, we may use stimulants to induce an appetite, but to suppose that young healthy animals, or ordinarily fed stock, require such materials, is a mistake. By using such things we shall decidedly destroy or injure the digestive system; and to pay from £25 to £40 a ton for the so-called cattle foods is most unprofitable. I might quote the opinions of Mr. Lawes and Professor Simmonds on this point, with which I thoroughly concur. Whilst fully allowing that several of the ingredients possess medicinal properties, Professor Simmonds states that the same objects may be attained by the farmer who mixes well-ground linseed meal with pea and bean meal, adding a small quantity of salt (and, I should say, locust bean meal), with a simple stomachic, nothing being cheaper than fenugreek mixed with aniseed. Such a compound need not cost more than 15s. to 16s. per cwt. If, however, I cannot advocate the so-called cattle condiments, but, on the other hand, consider them most extravagant, and often quite unnecessary, I greatly approve the mechanical condition in which these meals are prepared, and would recommend that now grinding mills are so improved, farmers should endeavour to prepare their food more carefully, and combine together a variety of materials; this leads me to the last portion of our subject, viz. :—

THE DIFFERENT METHODS OF FEEDING.

The digestive apparatus of the ox, sheep, and pig differ materially, and a study of this difference teaches us some general truths as to the description of food suitable for each. The ox possesses a larger proportion of digestive apparatus for a given live weight than any animal; the sheep comes next, the pig the least. Thus the ox, with his large and complicated stomach, and comparatively small intestines, evidently requires a bulky food, containing a considerable portion of indigestible fibre. The stomach must be filled, and therefore the food, to be of use, must be bulky. For every 100lbs. of live weight the ox has 11½lbs. of stomach, and only 2½lbs. of intestines. The sheep has much less stomach and more intestines, and altogether a smaller per-centage of digestive apparatus, indicating that whilst the sheep may and should consume some portion of woody matter, its food should contain a large proportion of starch and allied digestible matter—substances that are rendered soluble by the secretions of the intestines. The pig has only 1½lb. of stomach and 6lbs. of intestines to each 100lbs. of live weight—showing what we know by experience to be a fact, that this animal requires a concentrated and highly nutritious food, and would starve upon what would be a generous diet for the ox. The great proportion of intestine shows the necessity of a starchy kind of food. These are important points as indicating the descriptions of food that these three classes of animals will require. Thus, for instance, bullocks have been fattened entirely on good straw and oil cakes. Such a food would not do for sheep, as they require in addition a considerable portion of vegetables rich in starch, whilst pigs flourish best when fed entirely on meal.

It might have been supposed that on a subject so important, repeated experiments would have been carried out, and a formula arrived at, so that the process of feeding young, growing, and fattening animals, whether cattle, sheep, or pigs, would be as well defined and understood as any other manufacturing business. But an

agricultural experiment, especially upon live stock, is very difficult to carry out, and we are liable to be misled by results. We find that several well worked out experiments, as those of the Duke of Bedford, Messrs. Lawes and Gilbert, &c., have been made, but the object has been rather to determine the merits of different animals than to test the kinds of food. It is, therefore, with considerable hesitation that I venture to submit for your consideration the following mixture of food as likely to prove economical.

For animals growing and fattening at the same time (this will apply to the animal when weaned till killed), the amount of such food depending upon age:—

Linseed cake, or cotton cake	2 lbs.
Barley, or wheat meal, or palm-nut meal, or a mixture of all three.....	4 "
Beans or peas, or mixture	2 "
Louet beans or malt	1 "

In the above mixture we get a good proportion of the flesh-forming and fat-forming food. We might, in the later stages of feeding, increase the quantities of the linseed cake, and reduce or do away with the beans.

For sheep a mixture of the fat-producing food—such as linseed cake or palm-nut meal—with peas and mts crushed, in equal proportions, would make a good mixture easy to be used; whilst for pigs a mixture of barley meal, Indian corn if cheap, palm nut meal, and beans, peas, or lentils may be used. Suppose we give barley one-third, Indian corn and palm nut meal, in equal quantities, one-third, and beans, &c., one-third.

A great point in feeding is not to give a larger amount of artificial food than the animal can assimilate. Frequently we find excessive quantities of cake and corn applied, much of which must be wasted, or, at any rate, pass through the animal. Besides this, animals so over-fed are liable to inflammatory attacks, and, moreover, cramming, especially at an early stage, destroys the digestive powers. A great distinction, then, must be drawn between the supply of generous food suitable for developing the frame and growing bone, flesh, and fat in proper proportions, and the wasteful practice of stuffing an animal under a sort of idea that there cannot be too much of a good thing. Thus calves, during their first year, will not require daily more than from 1 to 2 lbs. of the first named mixture; from the first to the second year from 2 to 3 lbs.; and to be finished up with say 4 to 5 lbs., for we ought to have our animal, which has been growing and fattening ever since it saw the light, fit for the butcher at about 2½ years old. The practice of fattening old oxen is not nearly so common as formerly, still we may now and then have an opportunity of seeing how much food such animals will consume. If we begin when the animal is poor, we must supply bulk rather than quality, as there is a large vacuum to fill up; therefore to begin fattening a large beast with 8 or 10 lbs. of oil cake a-day is a radical error. I should say 6 lbs. of the mixture I have suggested, or of equal portions of cake and meal, would be enough for the first month; each succeeding month we may increase the artificial food from 1 to 2 lbs. a day. In no instance, and under no circumstances, do I believe it is right to use more than 6 to 7 lbs. of a rich, fat-producing food, whether that food be linseed oil cake or any similar material.

In the case of sheep, we may begin artificial food as soon as the lamb can eat. At about a month old a mixture of fine dust oil cake, bran, crushed oats, and finely bruised peas, may be used with good effect. The quantity consumed at this time is very small, but the animal learns how to eat, and when thrown upon its own resources, after weaning, runs to the corn trough and eats freely through the summer; and until the lambes on turnips, ½ lb. a day of artificial food is ample, 1 lb. from this time until Christmas, then ½ lb., and possibly, during the last month or two of feeding, we may give as much as 1 lb. a head daily. Stock lambs—those intended for breeding—should be fed like the others dur-

ing summer, and will generally do very well on a fair quantity of roots and dry food, without other helps, during the winter. With regard to pigs, it is more difficult to lay down any rules. The pig should have about as much as he can eat. There is one peculiarity in the habits of the pig that should be noticed—they are sure to do best on sour food; thus an old authority tells us—"The most profitable mode of converting any kind of corn into food for swine, consists in grinding it into meal, and mixing the latter with water, in cisterns, in the proportion of 5 bushels of meal to 100 gallons of water; this must be well stirred several times in the day for a fortnight, during warm weather, or for three weeks in a colder season; at the expiration of which time it will have fermented and become acid. In this state, and not before, the wash is ready for use; it ought to be stirred every time before feeding, and it will be necessary to keep two or three cisterns fermenting in succession, in order to prevent it being used before it is duly prepared. The difference of profit between feeding in this manner and giving the grain whole, or only ground," adds Mr. Young, whose words I quote, "is so great, that whoever tries it once will not be induced to change it for the common methods." I have never tried this method of feeding myself, but believe it is founded on experience and reason. The pig is the scavenger of a farm, and we know that when in a store state much of his food is in a state of fermentation. However, many may prefer a more modern system, namely, that of mixing the meal with boiling water, by which the insoluble cells that contain the gum and sugar of the grain are burst and the food is improved in quality. Cooking will answer for the pig better than for ruminants; indeed, I do not approve of cooking food for cattle or sheep. We may, in some instances, do well to prepare a soup of boiled cake, meal, &c., and pour it over dry chaff, or what is better, we may use our waste steam to pass through a mixture of chaff, pulped roots, and the artificial food we are using. Such a process must, however, be carried on every day, as beasts do not relish such food when it becomes stale. The mixture of chaff and pulped roots, in properly constructed bins, leads to a gentle fermentation, which adds to the value of the food; and such a mixture will keep good for at least 24 hours, so we may prepare one day's food in advance. This is, I believe, the best and the most economical plan that can be adopted. The quantity of roots will depend upon a variety of circumstances, which time will not allow me to discuss. To show the change in our practice, I may mention that a large bullock formerly ate 1½ to 2 cwt. of swedes per diem. Now, a better result is obtained by using three quarters of a cwt. pulped, with a mixture of hay, straw, and chaff; and, in many instances, animals are well fed upon 56 or 60 lbs. a day. Sheep still eat according to their live weight an immense weight of roots—in many instances as much as 20 lbs. a day. Now, this is not a perfect plan of feeding, and I believe the time is not far distant when a great change will take place, and sheep will be treated to pulped roots and chaff just as cattle are, only with a smaller proportion of straw and more roots. In this way an increased quantity of sheep will be kept in a healthier and, at any rate, in a more economical manner.

Gentlemen, I have done, and have only to thank you for the kind attention with which you have listened to my remarks.

DISCUSSION.

The CHAIRMAN said the paper they had just heard was remarkable for the amount of practical information it contained. Professor Coleman had scarcely given an opinion without stating the reasons on which that opinion was based, and those were founded on practical experience. He agreed thoroughly, as far as his own experience went, in a large amount of what had been stated in the paper,

but more particularly he agreed in this—that it was often the case that while a food by itself was of little value, that same food, if mixed with other ingredients, became invaluable. The great point was to get the proper proportions of nourishing and bulky matter to suit the animal they were feeding. But with cattle this was too often forgotten—that only a certain portion of nourishment could enter into the system; and, therefore, unnecessary expense was incurred by giving an excess of food. An animal with so many stomachs as a ruminating animal possessed, must, as Professor Coleman had remarked, have a large bulk of food, so as to enable the work of digestion to be performed in the ruminating system. That bulk need not of necessity be entirely of expensive food, but, at the same time, if the inexpensive food, such as chaff, were previously prepared by being made more or less succulent, it was rendered more suitable to the natural requirements of the animal. In this way he thought the application of steam for the softening of chaff, whether hay or straw, was of very great value. On his own farm the chaff was cut in a loft, whence it was discharged into a vessel of iron, about twelve feet square, and thickly perforated with small holes at the bottom. In the next building but one was a steam-engine, the waste steam from which was brought by a pipe underneath the perforated bottom of the vessel, so that there was thus sufficient heat to cook that vessel full of potatoes, if potatoes were the food employed. The steam cooked the chaff most perfectly, and when it was thus brought into a succulent state, it was then in a condition to be mixed with advantage with the more nourishing qualities of food which they chose to give the animal, and he found in that way there was great economy in feeding. It was only a few days ago he calculated the expense he was at in connection with a set of feeding boxes appropriated to fifteen head of cattle, when he found that at a cost of 11s. per head per week, they made on an average three pounds weight each per day, and it was only matter of further calculation to ascertain whether that was profitable feeding. He believed Professor Coleman to be correct in almost every respect, but more particularly he thought he was right in his remarks upon sheep feeding, and that it was useless to try to feed sheep with the same description of food as was suitable for the ox or the cow. He had fallen into that mistake himself, inasmuch as in hard winters he had attempted to make large quantities of artificial food, and he found, when chaff formed a large ingredient of that food for sheep as well as oxen, invariably the chaff was not eaten by the sheep, showing that it was not a suitable food for those animals. The late severe winter had been a very trying one in respect of feeding cattle. He (the chairman) lived in a cider country, and it occurred to him that the large quantities of apple pulp which were produced might be made available as an ingredient of food for his cattle. On mixing this with chaff and meal, to his great delight he found the cattle exhibited a great relish for it, which led him to manufacture cider to a very large extent, merely for the sake of the pulp with which to feed the cattle, and the result proved not only beneficial to the animals, but very economical. He had been told by his friend, Dr. Voelcker, that in Germany apples were largely used in feeding cows, and if that were the case, it confirmed the results of his own experience. In conclusion he would say, as far as he understood the subject, the paper with which they had been favoured was eminently a practical one, and could not fail to be serviceable to all who read it.

Mr. G. F. WILSON, F.R.S., said there was one kind of food on which Professor Coleman had laid considerable stress, viz., the palm-nut kernel. Having had much to do with palm nuts, he might state that the supply of them in Africa was enormous; and inasmuch as the value of the oil expressed from those nuts in this country was so much higher than that of the dull-brown, burnt oil as expressed in Africa, he thought, with the price obtained for

the cake, it must be a good paying process. He recollected some years ago, when pleuro-pneumonia was prevalent amongst cattle, Mr. Horsfall, of Otley, used cocoa nut oil as a remedy, with very successful results. Now the oil of the palm nut happened to be identical with that of the larger palm nut, the cocoa-nut; and it might be a question with agriculturists whether an oil similar to that which was found useful as a remedy in the case mentioned, might not also serve as a preventive of disease.

Dr. VOELCKER was glad to find that Professor Coleman had laid stress upon the condition of the food when given to the animal, as this was a matter too frequently neglected by those who gave opinions on the qualities of foods. They were too much in the habit of comparing merely the composition of one food with that of another, from which different conclusions were often arrived at as to the practical effect they were likely to produce when given to cattle. He thought this was a great mistake, for they knew by experience, that at one time the mangold was more nutritious than the turnip, and at another time it was the reverse. It was in this case entirely a question of maturity, for the same amount of woody fibre in a properly matured root was very nutritious, whilst in the unripe state of the root it was not so, and in the over-ripe state it was absolutely injurious; therefore the condition of the food materially influenced its nutritive value. Then there was another condition of food, viz., that which arose from keeping it in damp, unventilated places. He more particularly alluded to corn and concentrated food, such as oil cake, peas, beans, and lentils. Food, under such circumstances, was apt to become mouldy, and the microscope revealed the presence of certain lower vegetable organisms or fungi, some of which were decidedly poisonous to animals. He knew of many cases of such poisoning, which were clearly attributable to the fungi attached to food in the condition he had referred to. Professor Varnell, whom he was happy to see present, had informed him of a case of poisoning arising probably from musty food, and that gentleman would probably favour them with his experience. Whilst laying full stress upon the importance of this point, he could not agree with his friend Professor Coleman when he said that the absence of any analytical tests was one of the greatest impediments in securing pure linseed cake. They could examine, analytically, many kinds of cake for the presence of certain injurious materials. Rape cake admitted of an easy test. The presence of mustard was rapidly traceable by the formation of a pungent essential oil, when the crushed cake was mixed with lukewarm water, and allowed to stand for several hours. In addition to many other tests they had the microscope, which, in conjunction with the natural senses of taste and smell, was as good an analytical test as they could desire in such matters. One point in which he did not agree with Professor Coleman was in the statement that there was difficulty in procuring pure and clean linseed cake. There was a wholesome regulation in the seed-crushing trade of paying a price for the seed in proportion to its freedom from foreign substances. Beyond 5 per cent., which was the standard of foreign matter, an allowance in price must be made proportional to the amount of adulteration. There was no doubt, by paying a proper price, pure linseed could be obtained, and, therefore, pure cake; and he believed there was no indisposition on the part of the crushers to manufacture pure cake if they were paid a fair price for it. At the same time, he was aware that a great deal of oil-cake was sent into the market with the mark "P"—pure—upon it which was very largely adulterated by foreign matters. If farmers would have their cake tested under the microscope, which they could do at little expense, they might always secure good cake; and if there was a demand for that quality of food he had no doubt it would be supplied. With these trifling points of difference only, he entirely concurred in all that had been stated by Professor Coleman.

After a few remarks from Mr. VARLEY, Dr. CRACE CALVERT, F.R.S., said he had listened to the paper of Professor Coleman with the greatest pleasure; the more so as it had reference to a subject which, up to the present time, he believed, had received the attention of very few scientific men. If there was any knowledge on the subject amongst farmers, most of them had kept it to themselves, and he believed the public in general were not acquainted with the facts brought before them in this able paper. He had read a great number of papers from time to time respecting the feeding of cattle, and he had always been struck with the want of practical knowledge shown by those engaged in such researches, for those who had devoted any attention to this subject were, generally speaking, purely scientific men. There were on the Continent several eminent chemists who had given a great deal of attention to this subject, and at some future period he (Dr. Calvert) might have occasion to refer to some of their researches, and he would then be able, in a more forcible manner, to prove the truth of his assertion; but his point now was to show, in a marked manner as possible, the want of practical information which Professor Coleman's paper had gone far to supply. Thus it was found that Mr. Bousmault, one of the leading scientific chemists of Europe, attempted to feed some cows on carrots, as he thought it desirable food for them, but they decreased in weight and lost flesh. Why was this? Professor Coleman had given the explanation, that it was necessary that there should be bulk in the food as well as nutriment, and a great point was to give both in proper proportions. The Chairman had mentioned that in his own case he gave his sheep too much chaff in that instance; the bulk was as great as compared with the nutritive matter contained in the chaff. There was one very interesting point which Professor Coleman had referred to, namely, that it was not sufficient merely to give an animal a large amount of nitrogenated food, but in order to get the full effect from such food, it was found necessary that it should be mixed with a relative proportion of saccharine, amylaceous, or other heat-giving food. This confirmed the impression that he (Dr. Calvert) had had for many years, that such a relation between the various classes of food must be carefully preserved. He had been led to this view by the researches of one of the most intelligent chemists on the Continent, M. Ville, who investigated the application of ammoniacal salts and other nitrogenated manures to the growth of plants, and made this interesting observation, that if to plants a certain quantity of ammoniacal salts or nitrate of soda were supplied, only a limited amount of nitrogen was absorbed, but if to these nitrogenated substances phosphate of lime was added, the result was most favourable, the plants absorbing eight or ten times as much nitrogen in the same period of time; the absorption of the nitrogen being nearly in a direct ratio to the proportion of phosphate of lime added. With respect to the feeding of cattle, he was struck by the remark of Professor Coleman, that if they gave to cattle too much of one class of food, either of fat-forming or respiratory food, there was a loss. It therefore occurred to his mind that both for men and cattle (for what held good in the one case held good also in the other) there must be a finite ratio of food which time and science would reveal. He was satisfied, from his own experience, that the paper of this evening was one most valuable to the farmers of this country, because the science of the subject was mixed with sound practical knowledge, and that was the class of information which the farmers most required. Prof. VARLEY said reference having been made to his name in connection with the poisoning of cattle from the use of injurious substances in the food, he would briefly state the circumstances of the case. He would in the first place endorse the opinion expressed by Dr. Voelcker, as to the importance of the microscope in these investigations, and every feeder of cattle ought to possess of that instrument and know how to use it

properly. Two or three years ago he was professionally applied to on the occasion of the death of some valuable cows in an apparently mysterious manner. He found the cause of death to be splenic apoplexy. At first he gave an opinion that perhaps some fungi attaching to the food had been taken into the system, and on investigation he found that the cattle afflicted had been grazing on ergotised rye-grass. He was very glad Professor Coleman had laid so much stress upon diseases arising from indigestible food. He had met with many instances of deaths of animals from eating decorticated cake, and in some cases from feeding largely on bean straw, the straw not having been cut in the green state, but allowed to become over-ripened on the ground where it was grown. With reference to the circumstance alluded to by Dr. Voelcker, of fungi forming upon oats stored in damp places, he would mention a fact of importance to feeders of cattle. He was applied to from Leeds respecting the death of half-a-dozen horses, which occurred in about three days, and the cause of which it was difficult to trace. A quantity of the oats on which they had been fed was sent to him for examination, and he found that many of the grains were matted together by a sticky substance. Microscopical investigation showed the presence of distinct fungi as completely developed as mushrooms, though very minute. The sticky material proved to be jointed filaments, and the effects of eating that substance had been to produce the death of the horses. He tried the effects of the oats which had been sent to him upon other valueless horses, which died thirty-six hours after eating them, with the same symptoms exhibited. On an examination of the smaller intestines of the animals he found that the mucous membrane was thickened by a peculiar growth on the surface.

On the motion of the Chairman, a vote of thanks was passed to Professor Coleman for his paper.

Professor COLEMAN thanked the meeting for the attention with which they had listened to his paper, and he was glad it had led to some practical remarks in the discussion. With reference to the observations of Dr. Voelcker, as to the absence of analytical tests of food for cattle, he did not state that such tests did not exist, but that they were very seldom employed by farmers. He thought the want of appreciation of these tests was a great error on the part of consumers, and he certainly strongly advised the use of the microscope in such matters.

SOUTH LONDON WORKING CLASSES INDUSTRIAL EXHIBITION.

The prizes awarded to the exhibitors at this exhibition were presented on Saturday, the 1st instant, by the Right Hon. Viscount Palmerston, K.G.

The noble lord was accompanied by the Earl of Shaftesbury, the Right Hon. W. Cowper, Mr. Locke, M.P., Mr. Charles Gilpin, M.P., and many others.

Mr. Murphy, the honorary secretary, then read the report of the adjudicators, which stated that they deemed it desirable that, whatever the profits of the undertaking, they should be distributed among as many exhibitors as possible, rather than be expended in giving large sums to a few; this would account for the great number of prizes awarded and honourable mentions made. It was also deemed advisable that the awards should be of equal value in the different classes, and that a medal should be struck to commemorate the holding of the exhibition, a copy of which (in either silver or bronze) the holders of the superior prizes might take as a portion of the value awarded. The accounts had not yet been audited, but the distribution assumed a profit of £300. The first-class prize was £3, the second £1 10s., the third-class prizewinners would receive a bronze medal in case; and a highly ornamented card was prepared for those who had received honourable mention. Whatever sum of money might remain over when a settlement was made would be distributed in fair proportions, as per the vote of the committee. The

following is a summary of the awards:—First class, 35; second, 85; third, 123; honourable mention, 129; total, 372. It may be interesting to state, that out of 120 first and second class prizewinners, 110 have chosen that a portion of their prize should consist of a medal as per the prize design. Of these 77 have chosen silver, and 33 bronze mementoes of the Exhibition.

Lord Palmerston distributed the prizes, and then delivered an encouraging address, pointing out the favourable influences of such exhibitions. The Rev. Mr. Bowstead moved, and the Rev. Newman Hall seconded, a vote of thanks to Lord Palmerston.

DUBLIN INTERNATIONAL EXHIBITION.

The fine art collection from Rome will be very rich. A steamer, freighted with more than 100 works in sculpture and other articles, was to leave Civita Vecchia direct for Kingstown on the 1st of April. Among the artists who contribute works are the following:—G. B. Lombardi, 7 works; Benzoni, 16; Jacometti, 5; Adams, Carlo Voos, Bisetti, Rinaldi, Kowalsky, and others, 4 each; G. Lombardi, Barrotta, L. Bienaimé, Andrei, and Miss Foley, 3 each; Miss Stebbins, Muller, Forzani, Setaccioli, Luccardi, Provinciali, Galletti, Ferrara, and Larchetti, 2 each; Hogan, Achtermann, A. Bienaimé, Story, Baroni, Bizzi, Majoli, Moratilla, Rossetti, Valli, Prior, Di Giacomo, Salvatore, Obici, Hoffman, Schoops, Freund, Palombi, Giacomini, and Daly, 1 each. Mr. Randolph Rogers, the American sculptor, has consented to send a half-size figure of his well-known statue of "Nydia fleeing from Pompeii," from Bulwer's novel. Miss Hosmer has a group, and there is a colossal statue of Pius IX. in marble. There are also others, not specified.

Among the painters are Romako, de Rossi, Vertunni, Wider, Guerra, Bompiani, Muller, Bertacini, Brenan, Skirmunt, Farrel, Porcelli, Podesti, Strutt, A. Dies, Raggio, Rohden, Bartolomei, &c. Saulini sends twenty of his own cameos in shell and pietra dura.

Pieret sends a collection of very rare and valuable intaglios and cameos in pietra dura. Monsignor Ferrari (Minister of Finance) sends three portfolios and three volumes of engravings. Olivieri, specimens of book-binding. Cardinal Prince Altieri sends, by the arrangement of Professor Ponzi, an interesting collection of minerals and maps of the Alumières and Tolfa; Castrali, wax candles; Tucci, olive-oil; the Countess Mami sends sulphur products from Canale; Pozzi, artificial pearls; Dies, Rinaldi and Barberi send mosaics, the latter 41 specimens. The Pope also sends mosaics from his own works in the Vatican and specimens of his chromo-lithography. The Minister of Public Works sends specimens of the works of Vizia in cloth of silk and gold, as also specimens of Roman carpets; Martinori, two discs of Egyptian alabaster. Nazzari sends liqueurs, chocolate, and sweetmeats. Toni, the gun-maker, some guns. Vespiagnani, frame-work in ivory and gold; and Cavaliere De Rossi sends a most interesting plan of the Catacombs.

The colonies will be admirably represented as far as the restricted space allotted to them will allow.

From Natal, principally through the active instrumentality of Mr. John Robinson, a very fine collection has already arrived by the steamer Eastern Province, and a further consignment will come by the next mail steamer. Among the Natal collection are some most interesting curiosities and native manufactures, from Central Africa, collected by Mr. Barry and Mr. Baldwin, during their recent travels. The first-named gentleman has done what no European has done before, namely, crossed the continent from Walvisch Bay to Natal. He has been just a year on the way. The indigenous timber resources will be well represented in about forty varieties of colonial woods, contributed by Dr. Mann and Messrs. Topham, Brothers. Among the Bechuana articles "worth notice are the

poisoned arrows, the poison being obtained from small beetle; a large native pot, of superior workmanship to anything known in South Africa; ropes, twine, a fibres from the vicinity of the Great Lake; a sheathed knife from a tribe never visited by white men, living that unexplored coast district on the south of the Zambesi. The raw materials of the colony, cotton, wool, sugar, colonial spirits, coffee, maize, tobacco and cigars, preserved fruit, &c., are well represented. The collection also includes photographs, Zulu curiosities, including a most elaborate piece of Zulu wood carving, which took three years to complete. There are also karosses, or cloaks, jackal and other skins; two splendid lion skins, one thick-maned specimen; some magnificent bows, and other native weapons. The African Aid Society, the Church Missionary Society, the Liberian Consul-General, and others contribute African products.

Malta will make a fine display of lace and silver filigree.

OPERATIVE COACHMAKERS' EXHIBITION.

The prizes awarded at this exhibition by the judges—the Marquis of Lansdowne, Viscount Torrington, R. C. Mansell, Esq., Mr. Hall, of Long-acre; Mr. Holdway of Mount-street; and Mr. Rock, of Hastings—were distributed on Monday evening last, by the Right Hon. Lord Tauris, in the great room of the Society of Arts. On his lordship taking the chair,

Mr. G. N. Hooper, chairman of the committee, read an address expressing their satisfaction at the success of the exhibition, which had exceeded their most sanguine expectations. They had received the most cordial assistance from all parties, and hoped that this success would open a new era to employers and operatives of the coach-making trade, who would now, they hoped, maintain their place against the competition of foreign countries. They had enjoyed the advantage of a thoroughly independent committee of judges, and it had been considerably advisable to distribute the awards liberally where merit existed, notwithstanding the absence of competition in many cases. They hoped that this liberality would be as a stimulus for the future, and that a keener competition would be the result in the next exhibition. The address concluded as follows:—"Meeting as we do in the house of the Society for the Encouragement of Arts, Manufactures, and Commerce, we are reminded that a work small at its commencement may grow in the course of years to national importance. We cannot look forward to benefit the nation so extensively as this great and noble Society, but at a humble distance we have endeavoured to follow their example and originate what we hope may confer great benefit on the carriage operatives, and indirectly the whole nation to which they belong. All honour to the Society of Arts, which by its example and enterprise has endeavoured to elevate the character of working men; among its efforts the encouragement of Working Men's Exhibitions will doubtless effect much good, and facilitate many other good plans for helping them to help themselves, rather than allowing them to rely blindly on employers and the government in matters where personal character that is self-reliant can effect more than any external help whatever."

Lord Tauris then presented the prizes as follows:—

The Society of Arts prize for the best specimen of chasing, to J. Corbett; the Coachmakers' Company's bronze medals, to F. Humphreys, John Adecock, H. Filbeam, and J. Bassett; the Master of the Coachmakers' Company (Thos. How, Esq.), for the best design of an open and close carriage combined, to W. T. Allam; Mr. G. N. Hooper's prize of three guineas for a drawing of a barouche, W. C. Bolt, and of two guineas for a drawing of an hospital carriage, James Robinson; Mr. G. A. Thrupp's prizes of two guineas for the best stuffed cushion

in Morocco, Henry Headford, and for the best drawing of an under-carriage, Henry Semon; Messrs. Woodall's prizes of two guineas for the best panel of carriage painting, John M. Dean, and for the best finished pad and bridle, Edward Spendlove; and of one guinea for the best hand-sawn dash iron, Wm. Wood; Mr. Barlow's prize of two guineas for the best set of harness furniture, new design, to H. Birch; of half-a-guinea for the best working drawings of bridle fronts, R. Burgess; for the best specimens of hard-solder plating and soft-solder plating, D. Jones and W. Sheldon. The committee's prizes of two guineas, for the best specimen of heraldic painting, to J. J. Cowens; for the best specimen of decorative coach carving, J. Wyatt; for the best set of working drawings for an improved brougham carriage, A. Brewer; for the best specimen of sham caning, C. H. Fuller; for the best seat, the border sewn by hand, T. Robinson; for the best method of detaching fallen horses, J. Hamerton; for the best cushion, stuffed and quilted, A. Townsend.

Certificates of merit were next presented:—

For drawings of carriages to Joseph Butler; model of a landau, J. J. Norcott; drawing of improved hinge, Charles Toogood; model of improved hinge, a photograph and rule, John Weekes; apparatus for drawing C springs, Alfred Brewer; machine for drawing off fast-set axle boxes, J. Smith; painted spokes, sham caning and striping, W. Hewitt, jun.; a plain varnished panel, J. Gibb; imitation basket-work, &c., W. Ninham; six spokes painted, W. Simpson; panels of various colours, Henry Snee; a spring cushion, Carl Moller; a carriage seat, caned beneath and improved cushion, William Stephens; a model of a hammercloth, William Woolford; an improved awl, saving prick marking, Henry Wyatt; specimens of soft silver plating, George Coater; a case of lamps, the workmen at Mrs. Salisbury's; a panel of monograms, F. V. Hadlow; chased door handle and harness ornaments, Joseph Little; drawings, of drag, harouche, &c., S. H. Birch; coloured drawing of dress coach, J. Hewitt, jun.; various drawings of carriages, P. Rodwart; models of railway carriages, Wm. Hacker; brass model of carriage with portable railway, James Benwood; model of a state hammercloth, a straining joint, W. J. Murlis; a self-acting step to fold up under when carriage door shuts, H. S. Dobson; model of a brougham, J. T. Brown; new and inexpensive Venetian blind, J. J. Tattam; drawing of state harness, C. Muckersie; driving cushions of new designs, J. W. Berriff.

The prizes having been distributed, the CHAIRMAN said he regretted the absence of the Marquis of Lansdowne, who was much more intimately acquainted with the subject than himself. He hoped some of those who had been unsuccessful would not feel discouraged, for many of the articles now not successful might contain the germs of inventions likely to be valuable in future. The coachmaking trade required as much skill and ingenuity as any branch of industry. He observed with pleasure that the largest number of prizes had been given for what argued a high standard of education in the recipients. Twenty-one prizes for artistic merit had been awarded, thirteen for mechanical contrivances, and seventeen for manual skill.

A vote of thanks to the CHAIRMAN concluded the proceedings.

PARIS UNIVERSAL EXHIBITION, 1867.

The following is a translation of the official announcements published in the *Moniteur* of the 21st Feb., 1865:—

REPORT TO THE EMPEROR.

SIRE,—In conformity with your Majesty's order, I have had the honour to inform his Imperial Highness Prince Napoleon that the time has arrived for him to become the president of a commission which will be formed for the purpose of carrying out the decree of the

22nd June, 1865, for the holding of a universal exhibition in 1867. I have prayed his Imperial Highness to be good enough to communicate to me the general views on such an undertaking, suggested by the experience gained by him in 1855 and 1862, and then to call a meeting of competent men to discuss the preliminaries of such a subject. I now submit to your Majesty the conclusions drawn from these preliminary measures. The next important point being a good financial organization, I have referred to the results drawn from the two exhibitions in London and the one in Paris.

In London, in 1851, as well as in 1862, the initiative was taken by a number of persons who raised a guarantee fund, upon the faith of which the Bank of England supplied all the necessary funds at a moderate rate of interest. The commission for 1851 built a temporary structure, with a boarded area of 71,000 square metres (ground-floor and galleries); the receipts amounted to 12,700,000 francs, and, after defraying all expenses, a surplus of 5,800,000 francs remained. The commission of 1862 raised a building of 120,000 square metres in area, a part of which was designed to be permanent. The total receipts, with a grant of 250,000 francs from the contractor, just sufficed to cover the whole expenditure of 11,600,000 francs. At Paris, in 1855, the State, in undertaking the enterprise, was obliged to erect temporary buildings of 68,000 square metres, in order to supplement the area of 47,000 square metres provided by the permanent building erected by a company. The receipts amounted to 8,200,000 francs, and there was a total loss of 8,100,000 francs. It was ultimately determined to expend a sum of 11,000,000 francs for the re-purchase of the palace. The total expense, amounting to 21,000,000 francs, is covered partly by the possession of the Palais de l'Industrie.

In the face of these facts the question arises whether the system of commissions, such as conducted the two exhibitions in England, the one at a gain, and the other without loss, should be adopted; but, influenced by the subjoined conclusions, I am induced to give a negative reply.

In England the public willingly pays high charges to procure for itself the means of instruction, or to visit institutions devoted to science and art. Thus, in London, in 1862, a sum of 10,200,000 francs was received from 6,000,000 visitors, raised—first, by the minimum entrance fee of one shilling (1s. 25c.), and secondly, by season tickets and entrance fees varying from 2s. 6d. to £1 (3fr. 10c. to 25 francs). In France, until recently, the public were but little inclined to pay or bear such charges. Thus, in Paris, in 1855, 4,600,000 visitors only paid a sum of 3,200,000 francs; the entrance fees, at 20 centimes and at 1 franc, produced 2,600,000 francs, whilst those at 2 and 5 francs, with the sale of season tickets, produced but 600,000 francs. Assuredly better results may be expected in 1867; peace will be more fruitful than the war which was raging in 1855; the errors incident to a defective tariff will be avoided; finally, the public favour may be better relied on, if a competent commission punctually inaugurates the exhibition of 1867 on the day fixed for the ceremony. If it solves the problem of classification of the products of art and industry in a useful and attractive order, and if, above all, the productions of all the countries in the world are represented more completely than has been the case in previous exhibitions. Still it seems prudent to expect that, even under these conditions, the receipts at Paris in 1867 will not be so great as those in England in 1851 and 1862.

The financial success of 1851 was caused by circumstances which evidently will not occur again. The demands of the exhibitors for space were then satisfied by a building of 71,000 metres; but in 1862 even an area of 120,000 square metres was so much too small that the French exhibitors received hardly half the amount of space they applied for. The requirements of exhibitors of all nations had thus augmented, whilst public curiosity

remained stationary. These two tendencies foreshadow considerable deficit in all future exhibitions; and it appears that the way to lessen this deficit in 1867 will be, especially, to develop those branches of the exhibition which will augment the receipts in a larger proportion than the expenses. To attain this end it seems likely that a space of 140,000 square metres will be necessary. At London the chief sources of receipt, viz., the entrance fees, were increased by certain percentages taken by the commission on the profits of the contractors for the refreshment rooms, the catalogues, and on seven other sources of smaller importance. In 1862, for instance, these accessory receipts amounted to 1,000,000 francs. I do not think that in 1867, any more than in 1855, it would be well to have recourse to these financial means, which are hardly in accordance with our ideas. By organising monopolies the public is badly served, and thereby become discontented: no good is thus done to the chief source of receipts. These sorts of tax weigh, moreover, partly upon the exhibitors or their habitual representatives; and it seems injudicious to cast a burden upon so many people whom it is desirable to attract to these competitions, and who, often through a pure spirit of patriotism, are willing to bear the considerable expenses which arise from them.

In London, at the two preceding exhibitions, rewards of no intrinsic value were given to exhibitors. In France, since the Farnese Exhibition, in addition to the bronze medals, silver or gold medals have been given. I think it will be well to continue this custom, and even that it will be desirable to augment the sum devoted to prizes given in other forms.

In founding my opinion upon these considerations, I can foresee that the Exhibition of 1867 may, perhaps, require an expenditure of 18,000,000fr. I may add that the unfavourable contingencies which may happen to these kinds of enterprises do not seem likely to raise the expenditure above 20,000,000fr.; as for the receipts, they may probably amount to 7,000,000fr. or 9,000,000fr. I therefore come to the conclusion that the undertaking may cause a deficit of 12,000,000 fr. These estimates cannot vary much, whether they be applied to an entirely private undertaking, or to an exhibition carried out under the control and direction of the Government. No company having only a speculation as the object in view would propose to undertake the Universal Exhibition of 1867, unless guaranteed against inevitable losses by a subsidy, direct or indirect, at least equal to the anticipated deficit. Thus, from the financial point of view, the State would gain nothing by giving up all control over the preparation and conduct of the enterprise. Perhaps it might be said that the public interest which is the motive that induces the Treasury to participate in the expenses of this undertaking, does not permit the Government to hold itself aloof, and, moreover, it may be doubtful whether this independence would add to the *éclat*, utility, and to the success of the scheme. On the other hand, it may be admitted, without exaggeration, that in following the system of administration adopted by France in 1862, that is to say, in maintaining firmly unity of action, and strict superintendence, it may be, on this occasion, again possible to make some important reductions in the estimates. The utility of exhibitions has been clearly demonstrated by the considerations stated in the report which my predecessor had the honour to submit to your Majesty, and upon which the decree of the 22nd of June, 1863, was founded. Upon referring to these considerations I find that the State and the City of Paris have a sufficient interest in the realization of your Majesty's ideas, to justify their participation in such an expenditure, by means of a subsidy. This subsidy, limited to 12,000,000 francs, might be divided in equal portions between the Treasury and the City, which, by means of this grant, would be released from all responsibility if the undertaking entailed any unlooked for expenses. The Prefect of the Seine, with whom I have consulted on this point, does not hesitate to

think that the municipal council of Paris, which is always well disposed towards anything useful or generous, would not decline this participation. As for the balance estimated at 6,000,000 or 8,000,000 francs, it would be covered by the fees taken for entrance, and in case of their insufficiency, by the guarantee fund of a society formed for this purpose, under the auspices of the imperial commission. In the event of the total receipts, compared with the excess of expenditure above the 12,000,000 francs of subsidy given by the State and by the city of Paris, leaving a surplus due to the favour of the public, and the good management of the undertaking, it would be distributed in equal parts between the State, the city of Paris, and the guarantee society. By this means, Sir, industry and commerce, which are called to contribute to the *éclat* of this undertaking, and to gather advantages from it, will find themselves at the same time both taking part and interest, in the only way which the customs of our country permit, in its organisation and in the chances, either adverse or successful, which it may offer in a financial point of view. This would be at the same time a first step made in the direction of the initiative undertaken by our neighbours with so much firmness and success, and a homage rendered to the spirit of association. The natural consequence of this organisation would be to give to the guarantee society, in the working and superintendence of the enterprise, a part proportionate to its interest in it. The imperial commission might be, then, composed (in addition to its president and the ministers whose functions would qualify them for a seat at the board) of forty-one persons, chosen by the Emperor, from the competent and known persons of the State and the city of Paris, and of nineteen persons to be elected from among the guarantee society in the most practicable manner. The chances of success for future exhibitions would be increased by associating each time with the directing power persons possessing the experience of other exhibitions held previously in other countries. England being the only foreign nation which has up to the present time undertaken these kind of enterprises, I propose to your Majesty to include the names of three Englishmen in the imperial commission.

If your Majesty approve the conclusions of this report, I pray that the annexed decree may be signed.

I am, &c., &c., ARMAND BEHC,
Minister of Agriculture, Commerce, and
Public Works."

NAPOLEON,

By the Grace of God, &c.

Upon the proposition of our Minister of Agriculture, Commerce and Public Works.

Considering our decree, dated June 22, 1863, ordering an Universal Exhibition of Agricultural Products and Industry to be held in Paris, and opened on May 1, 1867;

Considering our decree, dated the same day, ordering the Universal Exhibition of Fine Arts to be opened on May 1, 1867, at the same time as the Universal Exhibition of Agricultural Products and Industry,

Have decreed and decree as follows:—

Art. 1st. The Universal Exhibition of Agricultural Products, of Industry, and Fine Arts, is placed under the direction and superintendence of a Commission, to be presided over by our well-beloved cousin, Prince Napoleon.

Art. 2nd. The following are nominated members of the Commission:—

His Excellency the Minister of State; His Excellency the Minister of Agriculture, Commerce, and Public Works; His Excellency the Minister of our Household and Fine Arts; Messrs. Darbier, Member of the Council of State, Director-General of Customs, &c.; His Excellency M. Baroche, Minister of Justice, &c.; Messrs. Elie de Beaumont, Senator, Member of the Institute; Boittelle, Préfet of Police; Michel Chevalier, Senator; Member of the Institute; R. Cobden, M.P. of England;

Lord Cowley, H.B.M. Ambassador at Paris; Deniere, late President of the Tribunal of Commerce, etc.; Denion du Pin, Administrator of the Messageries Impériales; Devincq, late President of the Tribunal of Commerce, etc.; Jean Dolfus, Manufacturer; Arlès Dufour, Member of the Chamber of Commerce of Lyons; Dumas, Senator, etc.; Dupuy de Lôme, Member of the Council of State, etc.; Favé, Colonel of Artillery, etc.; Fleury, Director-General of the Breeding Studs; His Excellency M. Fould, Financial Minister; Frémy, Governor of the Crédit Foncier; Garnier, Metal Merchant, etc.; Gervais de Caen, Director of the School of Commerce; Gouin, Member of the Chamber of Commerce, etc.; Lord Granville, the Lord President of the Privy Council of England; Baron Haussmann, Senator, Préfet of the Seine; Herbet, Member of the Council of State, etc.; Ingres, Member of the Institute; La Roncière le Noury, Rear-Admiral, etc.; Marquis de Lavalette, Senator; Leboulay, Member of the Municipality of Paris; Lefuel, Member of the Institute; Le Play, Member of the Council of State; His Excellency the Duke de Morny, President of the Corps Législatif; His Excellency M. Mague, Member of the Privy Council; Onfroy, late Manufacturer, etc.; Ozenne, Member of the Council of State; the President of the Chamber of Commerce of Paris; The President of the Tribunal of Commerce of Paris; Schneider, Vice-President of the Corps Législatif; Thouvenel, Senator.

The Commission will be ultimately increased to sixty members, exclusive of the President, the Minister of State, the Minister of Agriculture, of Commerce, and Public Works, and the Minister of our Household and Fine Arts.

Art. 3. In the case of the absence of H.I.H. the Prince Napoleon, the commission will be presided over by the Minister of State, or by one of the two Ministers of Agriculture, of Commerce, and Public Works, and of our Household and Fine Arts.

Art. 4. M. de Play is appointed General Commissioner.

Art. 5. M. de Chancourtois, Chief Engineer of Mines, is appointed Secretary.

Art. 6. Our Minister of State, our Minister of Agriculture, of Commerce, and Public Works, and the Minister of our Household and Fine Arts, are charged, each one as it concerns him, with the execution of the present decree.

Done at the Tuileries, Feb. 1, 1865.

NAPOLÉON.

Minister of Agriculture, Commerce,
and Public Works,
ARMAND BEHIC.

Fine Arts.

POMPEIAN CURIOSITIES.—The activity of the new Italian Government has produced, from beneath the *scoria* from Vesuvius that nearly two thousand years ago entombed the town of Pompeii, such an immense number of objects of utility, luxury, and curiosity, that the Museum of Naples is full to overflowing, and the authorities are puzzled how to turn these interesting relics of Roman civilization to the best account. Galleries, lofts, and cellars are crammed with objects from Pompeii, which continue to pour in from the excavations now being carried on with more ardour than ever. When Pompeii has been exhausted there will remain Herculaneum and other places over which the volcanic shroud has scarcely yet been disturbed; in short, the whole of the buried utensils and works of art, which time has not yet destroyed, of several large and populous towns. It is evident that no one museum or series of museums can conveniently receive and exhibit such a mass of antiquities, and all kinds of propositions have been made to meet the difficulties of the case. One scheme is to replace the various objects in the houses from which they came, and thus make a magnificent museum *in situ*, a taking pro-

posal, but which is rendered impossible from the immense cost of protecting the objects from further decay and ensuring their security. Another plan is to add a disused convent to the *Museo Borbonico*, but this would be only putting off the matter and making the collection more unmanageable, less capable of arrangement than at present. In fact, the greater portion of the objects collected are almost repetitions of each other, and the museum would be infinitely more useful to the archaeologist and artist if it contained only the best examples in each class, or, at any rate, just sufficient to illustrate every point, and thus bring all into view; and it appears now to be the prevailing opinion that the best method as regards the museum in question will be to preserve in it only unique and choice specimens. The next question is—What is to be done with the enormous remainder? And it is said that the government has determined on the enlightened and liberal course of distributing its superfluity amongst not only the other museums of Italy, which require completion, but also those of other countries. If such a plan should be carried out, the Italian government will earn the admiration and gratitude of every scholar and man of taste, and there is little doubt that such a generous act would not be without its advantages, and Italy might in return receive valuable articles in exchange from other countries. Such an interchange of the products of man's ingenuity would fill a worthy page in the future history of the nineteenth century.

Manufactures.

SUGAR MANUFACTURE.—Messes. Travers and Son, in their circular, speaking of the question of the sugar duties, say:—"Sugar, as presented to us by nature, is a colourless substance—a little troubled with saline matter, and largely diluted with water, but quite guiltless of treacle, glucose, or dirt. The juice of the sugar-cane contains about 80 per cent. of water, less than 1 per cent. of saline matter, and rather more than 18 per cent. of saccharine. The saline matter is easily got rid of, and if the water were evaporated at a low temperature, the residue would be colourless sugar, as nature intended. Let us now see how man has treated this excellent gift. The primitive mode of preparing sugar (we may safely say is, in many instances) to boil the liquor in open pans till the bulk of the water had evaporated, and the syrup had thickened. This syrup was then poured into porous vessels or baskets partially filled with clay, through which a large percentage of a dark-coloured viscous substance called treacle percolated, and the remainder, now styled raw sugar, was fit for market. Now, in this word *raw* there lurks a fallacy. It is correctly enough applied to silk or cotton in their unmanufactured state, but raw sugar is already a manufactured article; and, what is more, the term implies that such sugar is the necessary product of a primary process, and that a second process is requisite in order to convert the raw sugar into refined. Thousands of persons, no doubt, think so at the present moment. They regard brown sugar as a natural product—white sugar as a manufactured product. The idea is totally without foundation. In reality, the second process only undoes the mischief which has been accomplished by the first. Everybody knows that a piece of bread held in front of a brisk fire speedily becomes brown. This is because the sugary constituent in the flour is charred by the heat. And, in like manner, sugar-syrup, when boiled in an open pan at a temperature varying, according to the density of the syrup, from 220 to 250 degrees, becomes burnt or carbonised. Each delicate little white crystal puts on a brown coat, while the greater part of the molasses is produced through the same cause, being, in fact, nothing more than crystallisable sugar converted by excessive heat into uncrystallisable treacle. We can understand this rude

and ignorant mode of manufacture existing in former times, when the material arts were very slightly developed, and when sugar in the crudest state was hailed as an acquisition; but how comes it that at the present time, although we in Europe have invented vacuum pans, centrifugal machines, charcoal vats, and all sorts of appliances for turning brown sugar into white, that the bulk of our sugar is still shipped from the place of growth in what we may justly style an artificially-injured state? Is it that the colonial and foreign growers are too lazy and apathetic to make it any better? They are scarcely likely to be less enterprising now than they were two centuries ago, and we find that in the year 1680 the West India Islands possessed several establishments for producing white sugar. But two years later the French Government imposed an extra duty on the importation of these white sugars, and in 1684 it forbade the erection of any new colonial refineries. Two reasons were assigned for this narrow policy:—the first, that as sugar had become a valuable source of taxation, a less weight, paying consequently a less tax, would be imported if sugar were refined abroad, and freed from molasses and impurities before shipment; the second, because, in accordance with the false political economy of those times, it was considered necessary to bolster up the European refiner, and protect him from the competition of his colonial rivals. We now begin to see how it is that a clumsy and wasteful process of manufacture, begun in simple ignorance, has been artificially perpetuated up to the present time by Governments insisting that brown sugar should pay one rate of duty and white sugar another."

Commerce.

COTTON SUPPLY.—Messrs. George Fraser, Son, and Co., in their monthly prices current, dated 1st April. say, "Great as was the fall in the prices of cotton during the months of January and February, it was still greater in March, and amounted to an average of 4d. to 5d. per lb. on all descriptions of long stapled kinds, and of 2½d. to 4½d. variously on short stapled. As compared with the actual prices current prior to the stock taking at the end of December last, the quotations in yesterday's Liverpool circulars are marked at nearly but slightly over one-half those prices for American, Brazil, Egyptian, and West India descriptions, but at less than one-half for Bengal, China, and other short stapled descriptions, which are comparatively neglected by spinners even at the very low rates to which they have fallen. The causes of this great decline are to be found chiefly in the belief, increased by each successive arrival of news, of the approaching end of the American war, owing to the supposed inability of the South to continue the struggle for a much longer period; and from the weakness of the holders of cotton, owing to the enormous losses sustained, and yet to be sustained, on the unsold stocks, and the supplies yet on the water; as in none of the cotton-producing countries has the price fallen in anything like the same degree as in Liverpool. There has also been great difficulty in moving any large quantity of cotton out of first hands, owing to the deadness of speculation, and to the continued cautious policy of the trade in purchasing merely to about the extent of their weekly production. To these causes may be added the general want of confidence arising from past overtrading, and the enormous losses making on all the other trading articles of produce from excess in supplies stimulated by too easy credit, and which are now bearing their natural fruit in the almost daily occurrence of large failures, with the apprehension of others. Thus the Liverpool Cotton Market has been throughout the month in a state of semi-panic, and although for the moment the decline seems once more arrested, and during the last two days cotton has been in better demand, and at improving prices, there seems no feeling as yet of certainty that the

improvement will, like so many that have preceded it, prove more than temporary, inasmuch as the news just to hand from America is of the same tenor as that which created the previous depression, being regarded as generally unfavourable to the South. Apart from the expectations of a speedy end to the war in America, which, however probable, is as yet very far from certain, and may so remain until one or more great battles have been fought, and their issue determined, the decline in the price of the raw material would probably be found excessive, looking fairly at the facts of the case; for, taking the actual stock, as by yesterday's stock-taking ascertained to be in Liverpool, of 580,000 bales, and adding thereto the stock in London of 126,735 bales, we have a total of 706,735 bales against 388,083 bales in those ports at the same time last year. And there are now 74,207 bales in the continental ports against 58,392 bales at same time last year. These heavy stocks account in a great measure for the weakness of holders. But when we look to the supplies on the water from India and China, a very different aspect of figures presents itself; for we find that of all descriptions the quantities now on the way are only 339,788 bales against 582,980 bales at the same period last year, or a deficiency of 243,192 bales. It is likely that this deficiency will continue to increase, especially from China, which may not improbably cease its supplies entirely when the low price is known there to which its cotton has fallen; so that there may yet be a better future for cotton if the American war does not actually come to a speedy end, as it is likely the stocks in the ports have in such case attained their maximum or nearly so, and that with the increase of consumption to be anticipated from the raw material being at half the price of three months ago, the stocks in the ports will be slowly at first, but afterwards more rapidly lessened. But this will give no stability to the Liverpool market should the expectations of an end of the American war be kept up. It is more likely in such case, that without peace, with the war still going on, and only expected to end, we may have the staple brought down to peace prices."

ROYAL NATIONAL LIFEBOAT INSTITUTION.—The annual general meeting was held on Tuesday, the 14th March, at the London Tavern, the Duke of Argyll in the chair. The Institution had been enabled during the past year to increase considerably their life-saving fleet, which now numbered one hundred and forty-four lifeboats. The Committee adverted to the great loss which the lifeboat cause had sustained by the death of their President, Admiral the Duke of Northumberland, who for fourteen years had actively co-operated with them in carrying out the objects of the Institution. The most striking feature in the history of the Institution during the past year was the large number of splendid gifts, in the shape of the entire cost, amounting to £8,077 11s. 10d., of twenty-five new lifeboats, which had been presented to the Institution by philanthropic persons and collective bodies, in addition to an anonymous donation from "A Friend" of no less a sum than £5,000. During the past year the Institution had sent no less than thirty-four new lifeboats to the coast, and others were in course of construction. Transporting-carriages and boat-houses had been provided, with few exceptions, for the whole of the above-named lifeboats. The lifeboats of the Institution saved no less than 432 lives and 17 vessels during the past year, nearly the whole of them under circumstances when no other description of boat than a lifeboat could with safety have been employed. For these various services, and for the saving of 266 lives by shore-boats and other means, the Institution had granted rewards amounting to £1,539. It was stated that during the last two years about 12,000 persons had been afloat in the lifeboats of the Institution on occasions of wrecks and for practice, and that only three lives had been lost during that period. The lives of between 5,000 and 6,000 persons were placed by shipwrecks on our coasts annually in jeopardy; but owing to the prompt and unceasing exertions that were everywhere

made on occasions of shipwrecks, the actual loss of life amongst that large number of persons placed in peril did not last year exceed 450 lives. Much credit was undoubtedly due to the Board of Trade for their continued valuable and cordial co-operation with the Institution. The total number of lives saved from the establishment of the Institution, either by its lifeboats or by special exertions for which it had granted rewards, was 14,266. The committee referred to the cordial continued co-operation of the local Branch Committees, the Coast Guard, and the railway and steam packet companies. Legacies amounting to £3,365 had been received by the Institution during the past year.

Colonies.

NATAL.—A Natal paper thus speaks of the progress of the colony in the past year:—"Never before has industrious enterprise on the coast been so rewarded. Fact has outstripped anticipation. A series of favourable seasons has resulted in a sugar crop of unexampled abundance. From all that we can learn, after careful inquiry, it appears, that two-and-a-half tons per acre have been quite the average yield for the year. This is a yield realised very rarely to such an extent in other countries. On many estates, and those, too, that have been worked for some years, three tons and upwards have been realised. More than four tons, in a few cases, and from small patches, has been reported. Although some of the flat valley lands were touched by frost in July, the loss seems likely to be more than made up by the general goodness of the yield. It has been in many respects a good year for the sugar interest. Several new mills have been opened, and a large additional acreage has been put under cultivation. By having command of labour the planters have been enabled to extend their enterprises, and the high prices which ruled about the early part and the middle of the year tended to infuse a spirit of confidence and hope. The year's crop has probably been about 6,000 tons, or more than double what it was in 1863. Coffee culture has been growing rapidly in public estimation, and at this moment plantations are being formed on all hands. The success of the pioneer has induced others to embark their fortunes in an industry that is both pleasant and profitable, and that does not entail the wear and tear of mind and body inseparable from the larger liabilities of the sugar planter. Cotton has been less successful, and we cannot yet pronounce definitively as to the future of this staple. Small plantations continue to be carried on, and superior samples produced; but the profitability of its growth on a large scale remains a moot question. Arrowroot is advancing again, and the few engaged in its growth find it remunerative. Tobacco, throughout the colony, is a popular product. That our soil and climate are well fitted for its culture cannot be doubted. Both in the leaf and in cigars the quality of the article has been subjected to most conclusive tests. Time and experience are the only essentials required. We have great faith in the future of this plant, and are convinced that it will supply a means of livelihood to a large number of cottage farmers, as well as a source of opulence to larger growers and manufacturers. Flax we hope great things from, and the farmers who have tried its growth are confident still that the plant will thrive when once the preliminary difficulties are overcome. But we should like to see some other staple developed. For oats and oat-hay—the great stand-by in past years—there is only a partial market, and that a local one. Wheat only does in certain localities. The soil is really so fertile, and the climate is so genial, that it cannot be doubted there are many exportable articles which might be successfully acclimatised if the attempt were only made. Stock-farming continues the popular pursuit with our up-country colonists. Sheep increase as rapidly in numbers as they improve in character.

Large flocks are brought in from time to time from the other colonies, and the best blood is imported from France and England. Losses are experienced, of course, as they are everywhere, from some of those diseases to which sheep are heir, and from the neglect of proper care in sheltering them from the weather. The uplands are getting by degrees filled up with energetic young English farmers, whose efforts will, we hope, meet with success. Cattle and horse-breeding are, of course, menaced perpetually by the prevalent diseases. The character of both, however, is wonderfully improved. The beef we get now is quite different from the raw junk of old times, while in horse-flesh the introduction of some thoroughbreds has gone far to produce a very fair class of horse. On the whole, in respect of agriculture, the colony has every reason to be thankful."

PRODUCTS OF SOUTH AUSTRALIA.—The production of copper increases steadily in this colony, and should the projected railway to the far north be constructed, mines that will not pay, with present difficulties of transit and high rates of cartage, will most certainly be worked. The wine-growing interest is being steadily developed, and will soon be one of the most important industries. It was expected that, when the Colonial Parliament assembled, a measure would be introduced allowing free distillation for wine growers, coupled with a reduction in the duty of imported spirits.

NORTH AUSTRALIA.—The government agent has decided on fixing the site of the first town at Escape Cliffs, and it has been named by the Governor-in-Chief, "Palmerston." Natives have not shown themselves in the whole of the Hotham, or, as it will now be called, the Palmerston Peninsula. It is proposed to lay out about two-thirds of the city fronting the sea at the cliffs, which is a fine healthy situation open to westerly sea breezes, and the remaining portion at Port Daly, an inner harbour between the mouth of the river Adelaide and the Narrows. This harbour is safe from all winds, and is deep and capacious. The land around the basin which forms the harbour is low, some of it covered at high water spring tides to the depth of six inches, but there are other portions of the shore which, though low, are still quite free from any tidal influences, the water being deep enough for vessels of any size to lie within a few yards of the shore. Capital only is wanted to make yards and wharves for the convenience of shipping. There is a level road from Port Daly to Palmerston not less than six miles. The whole of Adam's Bay is a sheltered harbour, and for some years to come it is probable that vessels will not enter the inner harbour, as they are almost equally safe outside in a tranquil sea, and they can discharge cargoes by lighters with great facility at Palmerston itself. The stock stations for sheep will be in the Daly ranges, about sixty miles from Palmerston, to the south, and for horses and cattle the flats on each side of the river intervening, where the country is of the richest description, covered with tall grass, which it is scarcely possible to walk through, and abundantly supplied with fresh water by lagoons and running streams, which are found on both sides of the river at intervals of less than a mile. This country will probably form admirable breeding stations, having direct water communication for sixty miles with the shipping. Wool could be produced here as profitably as in the northern runs of South Australia; and there can be no doubt but that the flats of the Adelaide are well suited for cotton. There is a white sandstone which will be found, when quarried, to produce an excellent building stone. Lime, if not abundant, can be had by burning the coral, which can be collected from any of the coral reefs which everywhere fringe the north-west coast.

Obituary.

RICHARD CORDEN, M.P., died on Sunday, the 2nd April. He was born at the farmhouse of Dunford, near

Midhurst, Sussex, on the 3rd of June, 1804, and was thus in his sixty-first year when he died. The house in which he has latterly lived, and which was presented to him as part of the offering of the nation for his services in connection with the repeal of the Corn Laws, was built on the site of that on which he was born. Mr. Cobden's father belonged to the class of English farmers who for so long a period regarded Mr. Cobden as animated with the one sole idea of destroying their present fortunes and future prospects. At an early age he was sent to London to learn business in a warehouse, and he afterwards became a commercial traveller by accident, in consequence of having been requested to undertake the duty for one of his fellow employees who had fallen sick. Ultimately the houses which he represented disposed of the business to several of the employees, and among them to Mr. Cobden. He appears to have been successful in business, for it is stated that at the time when he first began his career as a public man his share of profits was not much short of £9,000 per annum. In 1834-5 he made a prolonged tour, visiting Egypt, Greece, Turkey, and the United States. On his return he addressed several letters, anonymously, on political and economical topics to the *Manchester Times*, and he also published a pamphlet, entitled, "England, Ireland, and America," by a "Manchester Manufacturer." The views which have now become so familiar as peculiarly his own were boldly stated in this his earliest work, namely, peace, retrenchment, non-intervention, and free trade as the true policy for England. He was elected for Stockport in 1841. Mr. Bright first saw Mr. Cobden about this period at Manchester. The Anti-Corn-Law League—then styled the Anti-Corn-Law Association—was formed in Manchester in 1838, by a body of earnest free-traders, who pledged themselves that their association should never be dissolved until absolute repeal of the corn laws had been obtained. It had its first great public demonstration in Manchester in January, 1839, and then adjourned to Westminster. On the 15th Feb., 1839, Mr. Villiers presented a petition to the House of Commons on the subject, signed by 40,000 people. His motion to hear the parties at the bar of the House was, of course, rejected, and the delegates, at the suggestion of Mr. Cobden, forthwith announced themselves as a league, pledged to agitate by every constitutional method for the attainment of their object. Money was raised, lecturers were employed to diffuse information throughout the country, and pamphlets were distributed. During several years the exertions of Mr. Cobden were unintermitting and herculean. In 1846 the free-trade struggle was crowned with success, and Mr. Cobden, who had sat as member for Stockport from 1841, was acknowledged by Sir Robert Peel as the chief reformer. It was then his old associates got up that great national subscription by which Mr. Cobden's services were acknowledged. Subsequently, while on the Continent, he received the compliment of being elected by the great constituency of the West Riding of Yorkshire. The course taken by Mr. Cobden with regard to the Crimean campaign and the Chinese question provoked much criticism, and, in common with many other politicians, he lost his seat in Parliament. Mr. Cobden filled up part of his leisure by a visit to America. During his absence a reaction set in, and he was elected in his absence for Rochdale. Lord Derby was now for some time Prime Minister, but on the return of Lord Palmerston to power, the Presidency of the Board of Trade was offered to Mr. Cobden, but declined. The latest service which he rendered to his country was the negotiation of the Treaty of Commerce with France. It is stated that M. Michel Chevalier, on reading a speech of Mr. Bright's suggesting such a treaty, wrote to Mr. Cobden that he believed the time had come when such a suggestion might be carried into effect. Mr. Cobden took up the idea earnestly, and communicated with Mr. Gladstone, by whom it was warmly entertained, and Mr. Cobden, having subsequently seen Lord Palmer-

ston, set out upon his mission, the success of which is so well-known. His labours appear to have been highly appreciated in France. The *Moniteur* in a recent article says:—"Cobden on his death-bed had the happiness to see the politico-economical work, so grandly understood by Napoleon III., shedding its rays over the whole of Europe, under the direction of a French statesman. Herein France was faithful to her initiatory mission. Richard Cobden was able to understand France, and he loved her. France will not forget him."

Notes.

EMBELLISHMENT OF TOWNS.—M. Warein, formerly *maire* of the town of Hazebrouck, who died a short time since, has left his property to be applied to the improvement of the place of which he was long the chief magistrate, on conditions which (presuming he had no relations) deserve to be noted for the spirit which dictated them. He regrets that the embellishment of the town has not progressed so rapidly as was hoped, and thinks that premiums offered to those who erect buildings with worthy frontages on the main streets and the grand Place of the town, may aid the work, and directs that during the next ten years at least that system be tried by means of the revenues from property bequeathed by him for that purpose. He says in his will that he does not desire to supply what the municipal authorities themselves are bound to effect, but to stimulate individuals to aid in the work of embellishing his native town, and expresses his belief that a few thousand francs a year spent in premiums will cause four or five times the amount to be expended in embellishments than would have been without such a spur, and that thus the working classes will each year benefit by so much additional work to be executed. If, in ten years, his executors do not find the plan to answer, they are to employ the property left in their charge to the foundation of an orphan asylum, or any other similar work not within the scope or the means of the local authorities, but to improvements which would not be effected with other means.

MODEL OF SEBASTOPOL.—A large plan, in relief, of Sebastopol is now being arranged in the gallery of the *Hôtel des Invalides* in Paris, where those of the fortified towns of France are placed. The plan in question is executed in plaster in twenty parts, and, when put together, will measure more than ten feet in length, and more than seven in width. It is on the scale of one in 2,000, and has been produced—from the lithographic plates attached to the journal of the operations of the French engineers, by Marshal Niel—by a sergeant ofappers, named Faure, of the Imperial guard, under the direction of Captain Riendel, who commanded a company of that division. It will be eventually placed in a portion of the Palace of Versailles occupied by the engineers of the Imperial guard.

SOLDIERS' GARDENS.—In the House of Commons on Monday night, Mr. W. Ewart asked the Under-Secretary of State for War whether he would state, or allow a return to be made, showing to what extent the cultivation of gardens by soldiers had been adopted in the army. The Marquis of Hartington said that a circular had lately been issued by the War-Office, giving greater facilities for the cultivation of gardens by the troops, and since then several applications had been received on the subject; but as there had not yet been time for many gardens to be placed under cultivation by soldiers, perhaps the hon. member would wait a month or two longer before moving for these returns, to the production of which there would be no objection.

Correspondence.

TOWN GARDENS.—SIR.—The very pleasant paper of Mr. John Bell, on the subject of town gardening, recalls to

my mind an article I contributed to one of the early numbers of *Once a Week* on a similar subject; not on the actual gardening, but on the means of acquiring space for the garden by the substitution of flat roofs for pitched roofs, adapting the Eastern architecture of dry climates to our own moist climate by better mechanical appliances. Our pitched roofs, with steep slopes, are simply a result of our imperfect materials, and their incapacity for tight horizontal joints; were they made like ships' decks, and as carefully looked to, there would be no difficulty in keeping them tight horizontally. But even the steep pitch, though advantageous in giving a better water-shed, has its disadvantages in the greater difficulty of keeping the tiles or slates from falling down, and above all, in the interminable trouble of lead or other metal in gutters and ridges. But we have now a material thoroughly well adapted for flat roofing, and capable of water-tight joints, a sawn slate, which would, I incline to think, make, on the whole, a cheaper roof in first cost, and certainly a less costly and troublesome one in repairs, and without taking up space or elevation with a miserable "cock-loft," a receptacle for soot, dust, and bad air through a series of years. The structure of this roof would be simple. Parallel wood beams, or beams of T-iron, of sufficient depth for the load, would stretch from front to back walls, or between the party walls, at the distance apart of the slates' widths, and overhanging the walls front and back some twelve inches, with a slope either way for water to run off into hanging gutters, communicating with vertical shoots. A light iron railing, breast high or more, should enclose this front and back and along the party-walls, separating one house from another. The openings for the chimneys and the roof door should be formed like ships' hatchways, with combings round them, by vertical slate ledges of sufficient depth. The edges of the slates, where abutting against each other, should be grooved in curves, and filled in with hollow piping of gutta-percha or india-rubber, forming, not a plastic caulking like that of a ship, but an elastic caulking, keeping all tight under vibration or expansion and contraction. The slates should be kept together in both directions through the whole length and breadth by light iron rods or bars below them, turned up at the ends. The lower sides of the horizontal beams should be ceiled as usual, with provision for allowing currents of air to pass freely through in warm weather, and for keeping the air stationary in cold weather, thus preserving an even temperature. In this mode what are ordinarily garret rooms with sloping sides would be square, and another floor—an open-air floor would be added to the house. To this floor water could be carried up by pipes, with or without a cistern, and be allowed to run away, after being used for irrigating gardens, as freely as on the ground surface, without any fear of leakage within the dwelling. This flat roof could be covered with a green-house all over, or with a simple vertical shelter to the north, some six feet high, possibly with a folding shelter to the east; and supposing all the buildings to be of equal height, there would be no reason why vegetation should not be as perfect as on a hill side in the country, except as regarded smoke, for the human breath ascending from below would rather act as a manure to the vegetation there than as an evil, and the vegetable absorption would get rid of the nuisance. With regard to smoke, that will gradually lessen as knowledge looms on us by the fact that smoke is wasted fuel, and that its consumption is an economy. The probable solution for this evil will be in leading the smoke into heated combustion chambers, burning away the visible products, and we know not how far the invisible gases and the wasted draught heat may yet be economised or made applicable to the roof gardens. It is quite within the range of possibility, and far from improbable, that our unsightly London chimneys may yet become objects of great beauty by being clothed in ivy, Virginia-creeper, honeysuckle, jessamine, monthly-roses, and other hardy plants. Even now such things exist in many parts of the City where fresh air blows; and a sheltered wall,

with a south or west aspect, in the City, might be as pleasant at Christmas as a sea beach under a southern chalk cliff, which makes an open-air green-house on a bright winter's day, with the thermometer at 15°. Any changes of this kind with existing dwellings must be limited, but it is worth the while of builders to study the question thoroughly for future erections, especially for the workmen's dwellings which will be in process of erection at railway termini. We can imagine a future time when, with smoke and sewage thoroughly utilised, and with house-tops covered with vegetation, this our London may become the healthiest, as well as the most beautiful, city in the world. We hear much of the beauty of Paris, but it is a beauty of the barrack kind—ornamental barracks; all done to autocratic order. The beauty of London will be that of individual growth—various and yet harmonious; varying, like every human face, and every vegetable leaf and branch; the great work of nature ever expanding, and not the work of the military pedagogue, cramping everything to a small set pattern like the wooden trees of a child's toy-box. Mr. Broome says that "air draughts are very damaging to plants," very probably giving vegetables cold. But the air cistern is a still worse thing. In the business house of Rothschild, in St. Swithin's-lane, there has been for some years an attempt to attain a fore-court garden, such as we see in Spain and France, but it is a very sickly affair, apparently from want of sun and ventilation. If the garden were removed to the top of the low range of offices, it would probably thrive and might have a three feet depth of earth. It would be a pleasant thing to see the great capitalist set this pattern to a wealthy city, only needing a good example to follow.—I am, &c., W. BARBER ADAMS.

GRANTS OF PROVISIONAL PROTECTION.

- Agricultural implements—475—G. Wright.
 Ammoniacal gas, motive power from—611—R. A. Brooman.
 Atmospheric air, apparatus for cooling—636—L. Perkins.
 Bags, mail and despatch—733—G. T. Bousfield.
 Balls, cricket, &c.—696—C. Huntley.
 Bales, hoops used in packing—663—W. J. Dornier.
 Barley, machine for thrashing—793—B. J. Webber.
 Blast furnaces, utilizing the waste gases of—478—J. CHF.
 Blast furnaces, hot air stoves for—666—J. CHF.
 Boxes, joints for—640—H. W. Wilmshurst.
 Boots, heels for—710—G. Evans.
 Bricks, machine for the manufacture of—767—C. W. Spark, T. S. Cross, and W. Adkins.
 Bridges, construction of—633—E. W. Young.
 Burglary alarm—664—W. H. Hudson.
 Button holes, machine for cutting—687—J. Garelly.
 Carriages, venetian blinds for—676—T. Stardin.
 Carriages, disconnecting horses from—683—P. Marvand.
 Carriage ways—661—W. H. James.
 Carding engines—693—J. M. Dunlop.
 Charcoal, apparatus for cooling—730—J. F. Brinjes.
 Cigars—695—C. L. Roberts.
 Clay, preparing kaolin or China—805—J. Wright.
 Coals, &c., drying and sorting—715—F. H. Warlich.
 Colour printing—721—I. Bagge.
 Cotton, apparatus for dyeing—617—S. Akerord.
 Cotton gins—673—E. Leigh.
 Dental operations, apparatus to facilitate—706—W. D. Napier.
 Drying apparatus—663—H. A. Bonneville.
 Electric piles—723—W. Clark.
 Explosive gases, indicating the presence of—666—G. F. Ansell.
 Fabrics, manufacture of—601—W. Clarke.
 Fabrics, mechanism for attaching buttons to—763—F. Wise.
 Fencing, socket for—775—A. G. Browning.
 Fire-arms, cartridges for breech-loading—706—F. A. Braendlin.
 Fire-arms, revolving—659—W. Clark.
 Fires, apparatus for blowing—765—J. Cookson and P. Billington.
 Flax, machinery for preparing—680—J. Samuel and S. Millbourn.
 Flax, apparatus for hatching—690—T. and H. W. Whitehead.
 Flax, machinery for scutching—627—A. Potts.
 Furnaces, &c.—692—E. B. Wilson.
 Furnaces, puddling, &c.—700—J. Wright.
 Gas burners—668—T. S. Hall.
 Gas and water, connecting tubes for conveying—669—V. Delperdange.
 Gas engines—731—H. Smith.
 Gas burners—609—W. M. Baker.
 Gasometers—761—C. H. Pennycook.
 Glasses, wine, &c.—693—J. M. Napier.
 Grain, apparatus for ascertaining the quality of—632—W. Banger.
 Hammer, steam—641—J. Dodge.
 Hats, dyeing straw used in the manufacture of—463—E. Carchoa.
 Harrows, drags, &c.—739—J. Seaman.
 Horses, shoes for—639—W. Clark.
 Hydraulic engine, valves for—791—J. Smith and S. A. Cheese.
 Illuminating, vaporizing hydro-carbon for—717—G. T. Bousfield.
 India rubber, cutting sheets of—656—B. Collins.
 Iron safes—653—A. E. Taylor.
 Iron doors—640—J. T. Harris.
 Iron ships, coating the bottoms of—681—R. P. Roberts.
 Iron bars, manufacture of puddled—777—E. T. Crawshaw and L. A. Lewis.
 Jewelry cases—803—J. J. Carter.
 Keyless watches—726—H. Chevrol.
 Lamps—753—A. V. Newton.
 Liquids, apparatus for drawing off—761—J. Walls.
 Lime, hyposulphite of—765—J. C. Stevenson.
 Machines, numbering—625—T. Craig and D. Carlew.
 Marine steam boilers—613—E. Humphreys.
 Meat, method of preserving—645—A. C. Henderson.
 Metal, engraving on—607—R. A. Brooman.
 Metals, apparatus for treating—697—R. M. Roberts.
 Metals, apparatus for rolling—701—E. Marsden.
 Metallic bedsteads—699—J. Atkins.

- Mining, apparatus for—737—J. Farrar and E. Booth.
 Musical instruments—741—W. Brookes.
 Nails, manufacture of—785—C. Farmer and T. Turner.
 Noxious gases, traps to prevent—698—J. Bragg.
 Oils, treading and purifying—732—C. Morfit.
 Paper, machinery for manufacture of—681—J. Park.
 Paper, machinery for manufacture of—633—J. H. Rawlins and J. Chappell.
 Pipes, core employed in the casting of—687—D. Hartley.
 Piston rods, packing for—647—F. Wise.
 Piles, apparatus for driving—697—D. and J. Maxwell.
 Property, safes for securing—728—E. Loyse.
 Pumps—751—J. Goodfellow.
 Railway, permanent way of—398—J. and J. Porter.
 Railway waggons, apparatus for coupling and uncoupling—680—D. J., and J. Morris.
 Railway trains, communication between passengers and guard of—679—A. Westhead.
 Safes—621—S. Phillips and J. Groves.
 Safes, fire and burglar proof—695—John Tann.
 Safes, &c., securing—702—H. Hill.
 Sheet metal, cutting, punching, &c.—795—G. Farmer.
 Shoes, manufacture of—637—A. E. A. Aubert and G. E. M. Gerard.
 Smoke vents—724—T. Kennedy.
 Smoking, tobacco for—616—W. E. Newton.
 Steam blowers—3133—W. Brookes.
 Steam generators—607—J. H. Johnson.
 Steel, manufacture of—657—R. Mushet.
 Steam generators—743—A. V. Newton.
 Steam generating—771—J. T. Romminger.
 Stones, apparatus for scouring—696—J. Hird and J. Walker.
 Stockings, manufacture of—725—H. Owen.
 Sugar, apparatus for refining—699—R. A. Brooman.
 Surgical operations, instruments for—691—C. Rahn.
 Switches, levers for railway—769—J. Deas.
 Tanning, treating hides for—631—W. Clark.
 Tee-piece and valve—684—C. Johnson.
 Temperature, securing low and uniform—719—A. V. Newton.
 Telegraphic instruments, apparatus for protecting—713—A. Bertach.
 Thieves and fire, safes for securing property from—714—E. D. Hodgson.
 Toast racks—694—G. Carter.
 Tubes, strengthening and ornamenting—667—E. Leaky.
 Tyres, manufacture of railway wheel—645—W. D. Allen.
 Vehicles, apparatus applied to—689—P. Rothwall.
 Vessels, side propellers for—603—L. Thomas.
 Vessel, registering the course steered by—787—W. Arthur.
 Walking sticks, apparatus for bending—682—J. and D. J. Jones.
 War, ships of—609—G. Haselme.
 Water, apparatus for supplying measured quantities of—707—R. G. Rattray.
 Weaving, looms for—683—S. Brooks.
 Window sashes, bolts for—672—W. Smith.
 Wrought iron, converting pig iron into—649—M. Morgan.

INVENTION WITH COMPLETE SPECIFICATION FILED.

- Sewing machines—819—B. W. Morrall.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

APRIL 19.—“On the Preservation of Natural History Specimens for Museum Purposes.” By B. WATERHOUSE HAWKINS, Esq., F.G.S.

APRIL 26.—“On the Wear and Tear of Steam-Boilers.” By F. A. PASEY, Esq.

CANTOR LECTURES.

The Third Course for the present Session will consist of six Lectures “On Some of the Most important Chemical Discoveries made within the last Two Years,” to be delivered by Dr. F. GRACE CALVERT, F.R.S., F.C.S. (Corresponding Member of the Royal Academy of Turin; of the Société Industrielle de Mulhouse; of the Société Impériale de Pharmacie de Paris, &c.), on Tuesday evenings, at Eight o'clock, as follows:—

APRIL 18TH.—LECTURE 2.—On the Discoveries in Chemistry applied to Arts and Manufactures (*continued*).

APRIL 25TH.—LECTURE 3.—On the Discoveries in Agricultural Chemistry.

MAY 2ND.—LECTURE 4.—On the Discoveries in Physiological Chemistry.

MAY 9TH.—LECTURE 5.—On the Discoveries in the Chemistry of Rocks and Minerals.

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

PRIZES FOR ART-WORKMEN.

The Worshipful Company of Salters contribute £10 annually to this Prize Fund.

The Council of the Society of Arts hereby offer prizes for Art-Workmanship, according to the following conditions:—

I. The works to be executed will be the property of the producers, but will be retained for exhibition, in London and elsewhere, for such length of time as the Council may think desirable.

II. The exhibitors are required to state in each case the price at which their works may be sold, or if sold previously to exhibition, at what price they would be willing to produce a copy.

III. The awards in each class will be made, and the sums specified in each class will be paid, provided the works be considered of sufficient merit to deserve the payment; and, further, in cases of extraordinary merit additional awards will be given, accompanied with the medal of the Society.

IV. Before the award of prizes is confirmed, the candidates must be prepared to execute some piece of work sufficient to satisfy the Council of their competency.

V. *Bona-fide* Art-workmen only can receive prizes.

VI. All articles for competition must be sent in to the Society's house on or before Thursday, the 14th of December, 1865, and must be delivered free of all charges. Each work sent in competition for a Prize must be marked with the Art-workman's name, or, if preferred, with a cypher, accompanied by a sealed envelope giving the name and address of the Art-workman. With the articles, a description for insertion in the catalogue should be sent.

VII. Although great care will be taken of articles sent for exhibition, the Council will not be responsible for any accident or damage of any kind occurring at any time.

VIII. Prices may be attached to articles exhibited and sales made, and no charge will be made in respect of any such sales.

IX. All the prizes are open to male and female competitors, and in addition, as regards painting in porcelain, decorative painting, and wall mosaics, a second set of prizes, of the same amounts, will be awarded among female competitors. If a female desire to compete in the female class only, she must declare her intention accordingly. The originals of the works prescribed may be seen at the South Kensington Museum, in the gallery at the entrance of the Sheepshanks pictures.

Casts may be seen at the Society of Arts, Adelphi, London, and the Schools of Art at Edinburgh, Dublin, Manchester, Glasgow, Birmingham, and Hanley in the Potteries.

Photographs, chromolithographs, engravings, rough casts in metal, &c., may be purchased at the Society of Arts, John-street, Adelphi, at the prices named.

The plaster casts may be obtained from Mr. D. Brucciani, 39, Russell-street, Covent-garden, W.C.

* * * The Council are happy to announce that several of the works which received first prizes in the competitions of 1863, 1864, and 1865 have been purchased by the Department of Science and Art, to be exhibited in the South Kensington Museum and the Art Schools in the United Kingdom.

1ST DIVISION.

WORKS TO BE EXECUTED FROM PRESCRIBED DESIGNS.

For the successful rendering of the undermentioned designs in the various modes of workmanship according to the directions given in each case.

CLASS 1.—CARVING IN MARBLE, STONE, OR WOOD.

(a.) *The Human Figure*.—One prize of £15 for the best, and a second prize of £7 10s. for the next best, work executed in marble or stone, after the Boy and Dolphin cast from a chimney-piece, ascribed to *Donatello*. Original in the South Kensington Museum, No. 5,896. Dimensions to be one-eighth less than the cast (linear).—This design may be adhered to strictly or adapted to any architectural purpose.

[Cast—Fifteen shillings; Photograph—One shilling.]

(b.) *Ornament*.—One prize of £10 for the best, and a second prize of £5 for the next best work, executed in marble, stone, or wood after a carved chair-back in the South Kensington Museum. Dimensions to be two-thirds of the cast (linear).

[Cast—Twelve shillings. Photograph—One shilling.]

(c.) *Ornament*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed in stone, after a *Gothic bracket* in the Architectural Museum. Dimensions the same as the cast. In this design the details may be improved by the introduction of small animals, and the human head may be changed according to the taste of the art-workman.

[Cast—Ten shillings; Photograph—One shilling.]

(d.)—One prize of £20 for the best, and a second prize of £10 for the next best, work carved in wood after a design by *Holbein*, as an *Inkstand* or *Watch-Holder* on three feet. Dimensions optional.

[Wood Engraving—Sixpence.]

(e.)—One prize of £15 for the best, and a second prize of £7 10s. for the next best, work carved in wood after the *Head of a Harp* of the period of Louis XVI., in the South Kensington Museum, No. 8,531. The head and bust only need be fully completed. Dimensions the same as the cast.

[Cast—Thirty shillings; Photograph—One shilling.]

(f.) *Ornament*.—One prize of £10 for the best, and a second prize of £5 for the next best, work carved in wood after an *Italian picture frame* in the possession of Henry Vaughan, Esq. Dimensions optional.—This design may be adhered to strictly or adapted in such manner as the workman may think fit.

[Photograph—Two shillings.]

(g.) *Ornament carved and gilt*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed in wood, carved and gilt after a *Console Table* in the South Kensington Museum, No. 6947, of the period of Louis XVI. The work to be carved roughly in wood, then to be prepared in the white by a gilder, then cut up or carved in the white by the carver, then to be gilt in mat and burnished gold. As such work may probably be executed by two persons, the prize will be apportioned as the judges may determine.

[Photograph—One Shilling.]

CLASS 2.—REPOUSÉE WORK IN ANY METAL.

(a.) *The Human Figure as a bas-relief*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after *Raphael's "Three Grapes,"* Dimensions—The figures to be six inches high.

[Photograph—One shilling.]

(b.) *Ornament*.—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after a *Tazza* in silver, date 1683, the property of Sir W. C. Trevelyan, Bart., now in the South Kensington Museum. Dimensions—The same as the model.

[Photograph—One shilling.]

CLASS 3.—HAMMERED WORK, IN IRON, BRASS, OR COPPER.

Ornament.—One prize of £7 10s. for the best, and a second prize of £5 for the next best, work executed after the portion shown in the photograph of the Pediment of a Gate (German work, date about 1700) in the South Kensington Museum, No. 5,979. To be adapted for use as a bracket. Dimensions—Twelve inches deep.

[Photograph—One shilling and threepence.]

CLASS 4.—CARVING IN IVORY.

(a.) *Human Figure in the round*.—One prize of £15 for the best, and a second prize of £10 for the next best, work executed after a miniature statuette (Italian), No. 304 in the South Kensington Museum; dimensions—the same as the cast; or after a medallion portrait of Flaxman, by himself, No. 294 in the South Kensington Museum; dimensions—to be reduced in height by one-half (linear).

[Cast—One shilling.]

(b.) *Ornament*.—One prize of £7 10s. for the best, and a second prize of £5 for the next best, work executed after a pair of *Tablets*, in the possession of John Webb, Esq. Dimensions—The same as the cast.

[Cast—One shilling.]

CLASS 5.—CHASING IN BRONZE.

(a.) *The Human Figure*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a reduced copy of "*Clytié*." A rough casting in bronze, on which the chasing must be executed, will be supplied by the Society at cost price—£2 10s.

[Plaster Cast—Three shillings and sixpence.]

(b.) *Ornament*.—One prize of £10 for the best, and a second prize of £7 10s. for the next best, work executed after *Goutier*, from a cabinet in the possession of Her Majesty the Queen. A rough casting in bronze, on which the chasing must be executed, will be supplied by the Society at cost price—3s. 6d.

[Plaster Cast—One Shilling.]

CLASS 6.—ETCHING AND ENGRAVING ON METAL—NICKEL WORK.

Ornament.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after arabesques by Lucas Van Leyden, A.D. 1528. No. 18,968 in the South Kensington Museum. To be engraved the height of the photograph, and, if round a cup or goblet, repeated so as to be not less than nine inches in length when stretched out.

[Photograph—Sixpence.]

CLASS 7.—ENAMEL PAINTING ON COPPER OR GOLD.

(a.) *The Human Figure*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after Raphael's design of the "Three Graces," executed in grisaille. Dimensions—The figures to be four inches high.

[Photograph—One shilling.]

(b.) *Ornament*.—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after a German arabesque (16th century). No. 19,003 in the South Kensington Museum. Dimensions—The same as the Photograph.

[Photograph—Sixpence.]

CLASS 8.—PAINTING ON PORCELAIN.

(a.) *The Human Figure*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after Raphael's "Two Children," in the cartoon of "Lystra." Dimensions—the same as the Photograph. This work is to be coloured according to the taste of the painter.

[Photograph—Ninepence.]

(b.) *Ornament*.—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after arabesques by Lucas Van Leyden, 1528. No. 18,968 in the South Kensington Museum, and coloured according to the taste of the painter. Dimensions—Double the size of the Photograph (linear).

[Photograph—Sixpence.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section IX.

CLASS 9.—DECORATIVE PAINTING.

(a.) *Ornament*.—One prize of £5, and a second prize of £3, for a work, executed after an ornament, from *Castel B. Pendino*, near Lodi, from a drawing in the South Kensington Museum, No. 1,150. Dimensions—length 4ft.—width, enlarged from the print in the same proportion.

[Coloured Print—One shilling.]

(b.) *Ornament*.—One prize of £5, and a second prize of £3, for a work, executed after a picture frame, in the South Kensington Museum, No. 7,890. Dimensions—5 feet by 3 feet 1½ inches, outside measure. The works to be executed on canvass, either with or without stretchers, in cool colours. Some lines of the mouldings may be gilt.

[Photograph—One shilling and sixpence.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section IX.

CLASS 10.—INLAYS IN WOOD (MARQUETRY, OR BUHL), IVORY OR METAL.

Ornament.—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after a specimen in the possession of the Hon. John Ashley. Dimensions—one-third larger than the Lithograph (linear).

[Outline Lithograph—Sixpence.]

CLASS 11.—CAMEO CUTTING.

(a.) *Human Head*.—One prize of £10 for the best, and second prize of £5 for the next best, work executed after Wyon's heads of the Queen and Prince Consort, on the Juror's medal of 1851.

(b.) *Animal*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after Wyon's

"St. George and the Dragon," on the Prince Consort's medal. Dimensions the same as the casts.

[Casts—Sixpence each.]

CLASS 12.—ENGRAVING ON GLASS.

Ornament.—One prize of £10 for the best, and a second prize of £3 for the next best, work executed after arabesques by Lucas Van Leyden, A.D. 1528. No. 18,968 in the South Kensington Museum. To be engraved the height of the engraving; and if round a glass or goblet, repeated so as not to be less than 9 inches long when stretched out.

[Photograph—Sixpence.]

CLASS 13.—WALL MOSAICS.

Human Head.—One prize of 10 for the best, and a second prize of £7 10s. for the next best, work executed after Bertini, of Milan. A preparatory drawing must be made, coloured, after the lithograph, on which the lines and disposition of the tesserae must be marked. The dimensions of the work should be regulated by the size of the tesserae proposed to be used, which size may be left to the choice of the artist. Although desirable, it is not necessary to execute the whole subject in actual mosaic, but if a part only be done, the eye must be in such portion. A coloured drawing, with tesserae, may be seen at the Society's house, and in the South Kensington Museum, and tesserae of two sizes may be obtained from Messrs. Minton, Stoke-upon-Trent, Messrs. Maw and Co., Brosely, Shropshire, Messrs. Powell and Sons, Temple-street, Whitefriars, and Messrs. Jesse Rust and Co., Carlisle-street, Lambeth.

[Lithographic Outline Coloured—Two Shillings.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section IX.

CLASS 14.—GEM ENGRAVING.

(a.) *Human Head*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a cameo portrait of Savonarola, No. 7,541 in the South Kensington Museum. Dimensions—the same as the cast.

[Cast—Sixpence.]

(b.) *Full-length figure*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a small Wedgwood medallion, No. 5,827 in the South Kensington Museum. Dimensions—the same as the cast.

[Cast—Sixpence.]

CLASS 15.—DIE SINKING.

Human Head.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after the head of the Prince Consort, by Wyon, on the Society's medal. Dimensions—half the size of the original (linear).

[Cast—Sixpence.]

CLASS 16.—GLASS BLOWING.

Ornament.—One prize of £7 10s. for the best, and a second prize of £5 for the next best, work executed after an original in the South Kensington Museum, No. 1,813. Dimensions—as given in the wood engraving.

[Engraving—Sixpence.]

CLASS 17.—BOOKBINDING AND LEATHER WORK.

(a.) *Bookbinding*.—One prize of £7 10s. for the best,

and a second prize of £5 for the next best, work executed in bookbinding, after an Italian specimen in the South Kensington Museum, No. 7,925. The work to be bound should be some classical author of the size given. Dimensions—the same as the photograph.

[Photograph—One Shilling.]

(b.) *Leatherwork*.—One prize of £7 10s. for the best, and a second prize of £5 for the next best, work of boiled and cut leatherwork for the outside covering of a jewel casket. Original in the South Kensington Museum, No. 7,768. Dimensions—one-half larger than the photograph (linear).

[Photograph—One Shilling.]

CLASS 18.—EMBROIDERY.

Ornament.—One prize of £5 for the best, and a second prize of £3 for the next best, work executed, either after a German example in the Green Vaults at Dresden, or an Italian Silk in the South Kensington Museum, No. 7,468, which may be adapted to a screen. Dimensions—according to the taste of the embroiderer.

[Photograph—German, Sixpence; Italian, One Shilling.]

CLASS 19.—ILLUMINATIONS.

Ornament.—One prize of £5 for the best, and a second prize of £3 for the next best, copy made from an Altar Card, attributed to Giulio Clovio, in the South Kensington Museum, No. 2,958, or from a MS. border, date 1450, No. 3,057, in the South Kensington Museum. Dimensions—one-half larger than the Photograph (linear).

[Photograph—Two Shillings.]

2ND DIVISION.

WORKS TO BE EXECUTED WITHOUT PRESCRIBED DESIGNS.

WOOD CARVING.

(a.) *Human figure in the round, in alto or in bas relief. Animals or natural foliage may be used as accessories.* 1st prize of £25 and the Society's Silver Medal. 2nd prize of £15. 3rd prize of £10.

(b.) *Animal or still-life. Fruit, flowers, or natural foliage may be used as accessories.* 1st prize of £10. 2nd prize of £7 10s. 3rd prize of £5.

(c.) *Natural foliage, fruit, or flowers, or conventional ornament, in which grotesque figures or animals may form accessories, preference being given where the work is of an applied character for ordinary decorative purposes, as representing commercial value.* 1st prize of £10. 2nd prize of £7 10s. 3rd prize of £5.

(By order)

P. LE NEVE FOSTER, *Secretary*.

Proceedings of Institutions.

EXAMINATIONS, 1865.—LIST OF LOCAL BOARDS.

* The Boards marked thus have been formed this year.

ABERDEEN.—Mr. W. Brebner, *Chairman*; Mr. H. Ambrose Smith; J. Cruickshank, LL.D., Prof. of Mathematics; J. S. Brazier, Prof. of Chemistry; R. Beveridge, M.D.; Messrs. W. Rattray, D. Mavor, and P. Cleland. The above constitute the *working* Local Board. The following are also *ex-officio* members:—The Lord Provost of Aberdeen; the Senior Baillie of Aberdeen; the

Dean of Guild, Aberdeen; John Manson; James W. Barclay, James Farquhar, John R. McKenzie, Baillie McHardy, Rev. J. Longmuir, LL.D.; Messrs. J. Duguid Milne, J. Miller, James Matthews, W. Ramage, T. Melville, W. Fraser, J. Berry, A. D. Milne, J. Bulloch, J. Grey, R. Leys, and J. Sinclair, *Mechanics' Institution, Aberdeen, Secretary*.

ALDERSHOT AND FARNHAM.—Capt. E. E. Mangles, *Chairman*; Messrs. W. H. Bayley, R. O. Clarke, Dewdney, B.A.; Sir C. W. Dilke, Bart.; Messrs. F. Eggar, T. Fabian, J. Grant; Dr. T. R. Jameson, M.D.; Mr. W. Ker; Rev. S. C. Morgan, M.A.; Capt. G. Newcome, J.P.; Messrs. B. Nichols, H. Poppleton, L.C.P.; E. Powell, S. Redgrave, Rev. Dr. Rule, Mr. J. Seymour, Dr. J. Shoolbraid, M.D.; Messrs. Sloman, C. Stroud; the Ven. Archdeacon Utterton; Messrs. T. White, T. Wonnacott, W. Hollest, *Treasurer*, and Barrow Rule, *Classical and Mathematical School, Aldershot, Secretary*.

***ALTON**.—William Curtis, Esq., *Chairman*; Messrs. W. Curtis, jun., Samuel Bickerton, Edwin Williams, and John Bryant, *Secretary*.

ASHFORD.—Rev. J. P. Alcock and R. H. Wright, M.A.; Messrs. J. J. Cudworth, R. C. Mansell, T. H. Vie, J. Keener, R. Rabson, F. Garaway, and Thomas Nesbit, 3, Dover-place, Ashford, *Secretary*.

BANBRIDGE (IRELAND).—Messrs. W. Waugh, J.P., *Chairman*, R. McClelland, *Vice-Chairman*, J. W. McMaster, J.P., D. Leonard, J. Hawthorn, M.D., J. Smith, jun., C.E., G. G. Tyrrell, W. Walker, G. F. Long, H. Finlay, J. Noble, H. Glass, T. Connor, and Alex. Black, (*Hon. Sec. Literary and Mutual Improvement Society*), *Secretary*.

BANBURY.—Rev. H. Back, *Chairman*; Messrs. T. W. Barrows, T. Bealey, F.C.S., R. H. Brooks, W. Johnson, F.R.A.S., D. Pidgeon, and R. H. Rolls; Rev. T. Russell, M.A.; Messrs. A. B. Rye, F.R.C.S., J. Stockton, and J. H. Beale, *Secretary*.

BARNET.—Revs. F. C. Cass, M.A., *Chairman*; T. R. White, M.A., and J. D. Bell; Messrs. C. T. Carter, S. J. Baldock, W. Baldock, and John Thimbleby, *Secretary*.

Parnaby, and Christopher Petty, *Secretary*.

THE DWELLINGS OF THE LABOURING CLASSES IN BAVARIA.

The Society of Arts, desirous of extending to some parts of the Continent its inquiry into the statistics of Model Dwellings,* addressed, in 1863, to Dr. Von Hermann, a Privy Councillor and a member of the Bavarian Government, a request to be favoured with some account of what steps had been taken in that country towards the improvement of the dwellings of the labouring classes, and the Minister of the Interior sent out a form (consisting of a series of questions) to the Government officials in all the districts of that country. The principal points in these questions were—The name of the building; the name of the proprietor; the purpose for which the building was intended; whether plans had been published; the architect's name; the date of opening; the area covered; peculiarities of construction or internal arrangement; the materials used and their prices; the management and regulations; the rental of dwellings or apartments; the number of residents in the preceding year, and the nature of their employment; statistics of mortality and sickness; financial statement as to cost of land; price of the building and of its fittings; annual income for rent, and outlay for repairs, insurances, &c.; the repayment of debts incurred upon the building; the local influences, such as the employments of the neighbouring population and the price of labour; the number of rooms in each dwelling, their area and height, whether there are one or more stories; the sanitary arrangements; the precautions against damages, damp, &c.; rent of each house, as compared with that of ordinary dwellings in the neighbourhood; annual outlay for repairs, &c.

In consequence of this application a number of documents and plans were forwarded to the Council, the following *résumé* of which has been prepared by Mr. Gilbert Redgrave:—

The buildings described have mostly been erected by the owners of factories, for the accommodation of their workmen. In two or three cases, however, these dwellings belong to building societies, who have erected them rather from pecuniary than from philanthropic views. These buildings are invariably grouped either in rows or blocks, and offer no example of single or double cottages as in England; they have sprung up either in manufacturing or mining districts, and in towns where manufactures are carried on. In Munich, where no manufactures of any importance exist, all attempts which have hitherto been made on a speculative footing have failed, partly for that reason, and partly perhaps because the laws relating to mortgage enable the possessor of a moderate capital to obtain the requisite building funds without the interposition of any company.

* See the Special Report issued in April, 1864.

There is, however, in the suburbs of Munich a class of buildings unknown in England, parts of which may be bought by different families.

Bavarian manufacturers, finding, as a rule, that their workmen were badly lodged, and on that account unhealthy, and that the paucity of dwellings created a scarcity of workmen, have from time to time built, in the vicinity of their factories, blocks of dwellings generally offering different degrees of accommodation, and varying considerably as to rent. The reports prove that the construction of these dwellings has brought about the most favourable results. The workmen and their families have improved in health and appearance. Mortality and diseases of the chest, arising from their former ill-ventilated and badly-warmed cottages, have decreased, and a better feeling has sprung up among the men, leading to the formation of benefit societies, reading clubs, and the like.

Careful statistics are given of the outlay for the several buildings, the materials used, &c.* The rough average cost of a number of the buildings amounts to £106 6s., with a maximum of £136, and a minimum of £68 per dwelling. Many of the blocks contain from twelve to twenty families. The architect's name is rarely given, as the buildings were carried out under the superintendence of the master-workmen of the several crafts. Most of these blocks have been erected within the last few years, but one or two date as far back as the commencement of the present century. The area which each dwelling occupies varies considerably, ranging approximately from 700 to 1,000 square feet. Most of the tenements have yards, and sometimes small gardens. The houses are generally built of brick, though a few are of wood, and they are roofed with tiles or slates. Judging from the elevations which have been forwarded, some trouble has been taken to render their appearance ornamental. The dwellings are in many instances under the supervision of the proprietor or manufacturer, who causes a weekly or monthly inspection to be made by a superintendent appointed for this purpose. The buildings are, as has been stated, mainly inhabited by the workpeople of the factories to which they are attached. The average number in a family seems to be seven. In houses of this class in towns the inmates are either small tradesmen, mechanics, or the employés of railways, post-offices, &c. In a building of this kind in Nuremberg, eighteen families inhabit three blocks. There are seven artisans, seven labourers, and the remaining four are employés at the railway or the post-office. The wages of the artisans, among whom there are three joiners, two shoemakers, one turner, and one locksmith, range from 16s. 8d. to 25s. weekly. The labourers earn from 11s. 8d. to 16s. 8d. weekly, and the men employed at the railway and post, from 50s. to 84s. per month. In another return from the town of Fürth, it is stated that among twelve families there are five joiners, two turners, three metal-workers, and two belt-makers. Many of the buildings have been so recently opened, that an estimate of the annual rate of mortality is impossible, but in one instance, among a manufacturing population of 600 workmen, there has been a daily average of only 2½ sick persons; and in Nuremberg, among 98 inhabitants of a building for workmen, only one death is recorded for the year 1863. As the land on which the buildings in question have been erected forms in most cases part of the grounds attached to the factory, no price of site is given, but in Nuremberg, where a building company had to buy land, the price paid varied from 1d. and 2d. to 7½d. per square foot. In Fürth the price paid appears to have been 2s. 7d. per square foot. In some places the manufacturers give the dwellings rent-free to their workpeople,

and even make provision for them in case of sickness or old age, and for their widows in case of death. By way of example, the following paragraph is given from a report, sent from the district of Middle Franconia, referring to the metal manufactory at Hammer, established in the year 1490:—"The patriarchal relationship which these manufacturers have always held towards their men, and which still continues up to the present day, in spite of the complete change which modern times have brought in this respect, has so good an effect on the community, that, although the manufacturer pays an annual poor-rate of 90s., the authorities have never been called upon to relieve any workman employed in this factory. This is owing to the fact that the manufacturer maintains the workmen and their widows in sickness and old age." Workmen so treated are certainly favoured beyond most of their class.

When a rent for the lodging is required, it varies considerably with the accommodation afforded. A fireman pays from £5 to £10 per annum for a very good house or tenement; a workman with a family has a dwelling varying in rent from £2 to £6 per annum; and unmarried people pay from £1 to £2 10s. a year for one or two rooms. The rent is paid quarterly or yearly. The repairs, which cost about 1 per cent. on the capital, are defrayed by the proprietors. The population living in the country round these dwellings consists of farmers and their labourers. The latter earn from £4 5s. to £5 a-year with board and lodging, and the day labourers from 1s. 2d. to 1s. 8d. per diem. The workmen in the factories or mines are similarly paid. The adult men receive from 8s. 4d. to 25s. per week; the adult women, from 6s. 8d. to 8s. 4d.; and the boys, from 4s. 2d. to 5s.

The accommodation varies according to the class of workpeople for which it is designed. In towns we find workshops attached to the houses, and sometimes cellars and roof space. A foreman may have a living room, a kitchen, two bedrooms, a cellar, and a loft; workmen and their families have a kitchen, a bedroom, and a loft or cellar; and single men, or factory girls, a single room. The sizes of the different rooms in these houses appear to be about the same as in model dwellings in England. The Bavarian manufacturers being aware how much cheaper it is to provide a given amount of accommodation in a high piled building than in one occupying a comparatively large area, have adopted the system of flats, repeating the same arrangement in many floors with a common staircase.

The buildings are inspected from time to time by the proprietor or his agent, and the inhabitants are bound down to certain rules, the infraction of which will expose them to penalties or dismissal. It may be interesting to quote a few of these rules, which are obtained from the report on the cotton factory at Kolbermoor:—"Rule 4. Every part of the house, both the bedrooms and the kitchen, must be thoroughly cleaned once a week, and the windows at least once a month. The pathway in front of the house, the steps at the entrance, and the staircase, must be cleaned every Wednesday and Saturday, and this work must be performed alternately by the dwellers in the upper and lower story. Rule 5. To guard against vermin the beds must be aired daily, and the straw mattress must be filled with fresh straw in the spring and autumn. Both for the sake of cleanliness and to guard against fire, the straw must not be used loose in the bed, but must be enclosed in a proper ticking. The bedding must not be laid on the floor, but must be placed on bedsteads, or at least on trestles. Rule 9. The little garden belonging to each dwelling must be kept in good order, and be well cared for. Gardens which are not properly cultivated, or are visibly uncared for, will be taken from the family to whom they belong, and will be made over to some one else. Rule 13. No inhabitant may keep beer in casks in the house, and no business may be carried on in the house without the special permission of the manager."

These four examples will serve to show how completely these lodgings are under the supervision of the manu-

* The average price of materials in Bavaria appears to be as follows:—Bricks, 45s. per thousand; freestone, 4d. per foot cube at the quarry; tiles, 50s. per thousand; slates, 42s. per thousand; fir timber (rough), 10d. per foot cube.

ture. The remaining rules relate to lodgers not being members of the family, to the moral behaviour of the inmates, to quarrelsome families, and to the punishments for the infraction of rules, which consist, for a first offence, of a fine of 10d., and for a second, of dismissal from the house, and even, in bad cases, from the factory. In towns these buildings are under the supervision of the sanitary police, and are subjected by them to very stringent rules.

In most cases, when a rent is taken for the use of the dwellings, it is about equal to what would be charged for an ordinary dwelling in the neighbourhood, with, however, very inferior accommodation. The model dwellings, being supplied with good stoves and good means of ventilation, are a great inducement to the workmen to leave their former wretched homes, and consequently it appears that all the buildings, however recently they may have been opened, are fully inhabited. The great difficulty in planning sets of dwellings in several stories is to ensure privacy to each family; but it does not appear that the German manufacturers have in any instance adopted the external gallery system, which is one of the best expedients hitherto imagined for attaining that object. It is pleasing to see the friendly relations which exist in Germany between the families inhabiting the same house, resulting in clubs and savings banks of the same character as our benefit societies in England. The printed rules of several of these societies, which have been sent over, might serve as specimens for such undertakings in our own country.

Fine Arts.

PARIS ANNUAL EXHIBITION.—It appears that the report that there would be no exhibition of works of art next year in Paris, in consequence of the great international gathering to take place in 1867, is incorrect, and that the annual exhibition will take place in 1866 as usual. The reason given against any break in the chain is a good one, namely that, as works which have been seen previously in public will be admitted in 1867, there will not be room for an extraordinary number of new pictures. Another reason might also have been given, namely, that the system of art education in Paris produces such an undue number of artists—good, bad, and indifferent—numbers of young men, who would be more profitably occupied in other callings, being led to study art for years, only to find out at last that they have mistaken their vocation, by the lure of gratuitous or cheap art-education—that the number of works sent for exhibition increases every year. The total number received by the jury of the *salon*, to open on the 1st May this year, is said to amount to six thousand; a larger number than the managers have ever yet had to deal with. Speaking of the annual exhibition, it may be mentioned that M. Fleury, member of the Academy of the Beaux Arts, and director of the new school, has been selected from the list of the jury elected by the artists to preside over that body.

EXHIBITION OF FINE ARTS AT LYONS.—This exhibition closed the other day, and the report of the results shows the great value of these local exhibitions in France. The value of the various works sold out of the exhibition, 129 in number, amounts to more than £8,214. Of these, three were purchased by the municipal authorities for the public gallery of Lyons, for eleven thousand francs (£440); sixty-two by the Société des Amis des Arts, by whom the exhibitions are arranged, for 30,960 francs (£1,238); these also will be, in a measure, public property; and the remaining sixty-four by private individuals for 37,905 francs (£1,516). This is a result of which Lyons may well be proud. When we reflect that there is scarcely an important town in France in which something of the kind does not exist, we cease to be surprised at the dissemination of the taste for art which pervades the country.

HISTORICAL PAINTINGS IN THE HÔTEL DES INVALIDES.—M. Bénédicte Masson has just completed the first of his works, in the great court of the Invalides, the "Epoch of Charlemagne," which is to be opened to visitors in the month of May. The wall is being prepared to receive the second of the series of illustrations of French history.

DECORATION OF THE BERLIN GALLERY.—It is said that the painter Kaulbach has very nearly completed his labours for the decoration of the walls of the Musée. It is stated that the sums already paid to the artist for material outlay only amount to about £3,720.

PHOTOGRAPHIC EXHIBITION IN PARIS.—The Annual Exhibition of Photographs is appointed to take place in the same building and at the same time as that of the pictures and sculpture, namely, the first of May.

Manufactures.

EXHIBITION AT BORDEAUX.—An interesting exhibition is announced to take place at Bordeaux, to consist of the agricultural and industrial products of France, Spain, and Portugal. The undertaking is started by the Philomathic Society of the town, with the concurrence of the Chamber of Commerce, and the countenance and aid of the French, Spanish, and Portuguese Governments, the local authorities of the department, and the municipality of the town itself. The exhibition is to occupy an extensive building, now being raised for the purpose, on the Grande Place, one of the finest public promenades in France, and its doors are to be opened on the first of July. The management has an agent in Paris.

INDELIBLE INK.—One more contribution to the list of new and indestructible inks, real or supposed, comes from Germany. The recipe is as follows:—20 grains of sugar dissolved in 30 grains of water, and the addition to the solution of a few drops of concentrated sulphuric acid; the mixture is then heated, when the sugar is carbonized by the action of the acid. It is said that the writing is not only of a solid black colour, but that the acid resists the action of chemical agents.

A NEW AMERICAN SILKWORM.—It appears, from *Silliman's Journal*, that after numerous experiments, Mr. L. Trouvelot, of Medford, Mass., has succeeded in rearing successfully, and in great numbers, *Attacus Polyphemus* Linn., and in preparing from its cocoon an excellent quality of silk, possessing great lustre and strength, and pronounced superior to Japanese and all other silks, except the best Chinese, by competent judges. The silk is unwound by a simple process perfected by Mr. Trouvelot, each cocoon yielding about 1,500 yards. This insect is very hardy, being found throughout the Northern States and Canada; and, as it feeds upon the leaves of oak, maple, willow, and other common forest trees, may be reared easily in any part of the country. Mr. Trouvelot has gradually increased his stock from year to year, by raising young from the eggs of the few individuals first captured, until he has at present seven waggon-loads of cocoons, the entire progeny of which he proposes to raise during the coming season. The first public notice of his experiments with this insect was given by Mr. Trouvelot at a meeting of the Institute of Technology, at Boston, about a year ago, when he exhibited specimens of silk manufactured from it, both natural-coloured and dyed.

Commerce.

NEW CHARTS OF THE FRENCH COAST.—The Minister of Marine has presented a report, which has been approved by the Emperor, on the necessity of a complete revision of the charts of the French coast, and a re-publication of the *Pilots Français*. The charts now in use date from 1816 to 1838, and since that time great changes have

taken place in the coast line, as well as in the profile of the bottom. It is therefore determined that the whole shall be completely revised, and it is said that the work can be completed with the ordinary means at the disposition of the Director-General of Maritime Charts and Plans, without drawing upon any extraordinary resources whatever.

UNITED KINGDOM.—STATISTICS OF THE PAPER TRADE.—Quantities of paper (except hangings) imported and exported:—

Years.	PAPER IMPORTED.			PAPER EXPORTED.					
	For printing or writing.	Other kinds (except hangings).	Total.	British.			Foreign.		
				For printing or writing.	Other kinds (except hangings).	Total.	For printing or writing.	Other kinds (except hangings).	Total.
1862	115,927	73,506	189,432	93,190	36,136	129,326	9,500	3,608	13,108
1863	133,401	69,282	192,683	111,612	49,006	160,618	14,565	3,618	18,173
1864	183,064	89,653	242,607	116,071	51,734	167,805	23,452	4,386	28,438

Value of paper (except hangings) imported and exported, and quantities of rags imported and exported:—

Years.	Total Imports (except hangings).	Total Exports (except hangings).		Difference in favour of Exports.	Rags, &c. for Paper- making.	
		British.	Foreign.		Imported.	Exported British and Foreign.
1862	420,948	441,103	31,509	51,664	tons. 23,942	4,715
1863	440,198	548,267	45,463	183,511	45,447	4,429
1864	522,447	550,092	not ascertained.	...	67,817	2,663

The foregoing figures go to prove that the British paper trade was not so greatly interfered with as was supposed would be the case, by foreign-made papers. Although the import of foreign-made papers has been steadily on the increase since the removal of the excise duty, the make and export of British papers have also largely increased. Instead of there being, as alleged, a deficiency in rags and other materials for making paper, the imports have more than doubled in the last three years, the increase being chiefly made up of exports, palm leaves and other vegetable fibres from the shores of the Mediterranean, which are found well suited for common printing papers.

Colonies.

AUSTRALIAN UNION BENEFIT SOCIETY (SYDNEY).—From the last report it appears that the total number of members is 131; that the income of the past year was £346 16s. 4d. (of which £233 4s. 6d. was received as monthly contributions, and £118 11s. 10d. as interest), and the expenditure, comprising the medical officer's salary, sick allowances, printing, &c., amounted to £215 1s. 5d., leaving a balance in hand of £131 14s. 11d.; and that the society has the large sum of £1,785 10s. 2d. invested, bearing interest. These facts show that the society is in a prosperous state.

PORT ADELAIDE.—The numbers of immigrants and emigrants at this port from the commencement of the year 1864 to the 14th December last, as shown by the official returns, are as follows:—Immigrants, 5,517; emigrants, 2,471; increase of immigration over emigration, 3,046. The above totals include the following, as shown in the classification adopted in the returns:—

Classes.	Immigrants.	Emigrants.
Adults, Males	2,985	1,446
" Females	1,636	652
Children	896	373

Obituary.

JOHN CASSELL, the well-known publisher, expired at his residence in Avenue-road, Regent's-park, on Saturday, April 1st. Born in Manchester on the 23rd of January, 1817, he has died at the early age of forty-eight. Thrown in early life by the fortunes of his family among the working classes, he acquired a knowledge of their character and condition, which was the foundation of his future usefulness. He served a hard but salutary apprenticeship to manual labour, and so fitted himself to become the exponent of its wants and its claims. Realising the disadvantage of the defective education common to his class at the period of his early life, he was almost solely indebted to his own persevering exertions for the knowledge he acquired, and, in after years, so well applied. Seeing within the range of his own observation the evils accruing to the working classes from intemperance, he threw himself with all the zeal and energy of his youth into the temperance movement, which was about that time originated, and as an advocate of the cause he obtained a wide popularity, and exercised a powerful influence. Arriving at manhood, he successfully established himself in extensive commercial undertakings, and while in these pursuits his desire to benefit the classes whose educational needs he was so well acquainted with, induced him to commence, from philanthropic motives, the publication of those well-known works designed for the intellectual, social, and religious elevation of the people, and specially adapted for their requirements. These works, originating from a benevolent motive, soon formed the nucleus of what has become, in the hands of himself and his partners, Messrs. Petter and Galpin, a great publishing business. In private life he was much respected. Few men had so long a list of friends, and it included men of all ranks and conditions, by whom his friendship was considered a privilege, and from whom his gentle and noble qualities won respect and esteem.

Notes.

MORTALITY IN FRANCE.—The Statistical Society of France has issued a statement which demands serious consideration, namely, that while the mortality of London at present surpasses the average of the last ten years, that of Paris has diminished from 31 in the thousand in 1846 to 25 in 1864. This is but a loose way of putting the case, as the general amelioration in the case of London is omitted, and only a bad year selected for the comparison. However, leaving out all question of London, it is very important to note that the rate of mortality in France has materially diminished. It appears that that of Paris fell from 3.12 per cent. in 1845 to 2.50 in 1862, and of Toulouse from 2.62 to 2.20 per cent., the last-named town exhibiting as low a mortality as the whole of France. The great towns stand in the following order with respect to mortality:—Rouen presents the highest rate, or 3.13 per cent.; then come Marseilles, Lille, Paris and Bordeaux equal, Lyon, Nantes, and Toulouse. The improvement during the period named has not been in the same ratio, but as follows:—Bordeaux exhibits a diminution of deaths to the extent of 0.89 per cent.; Lyons, 0.66; Marseilles, 0.63; Paris, 0.62; Lille, 0.50; Rouen, 0.47; Toulouse, 0.42; and Nantes, 0.32 per cent. only. One reason why Paris has not benefited in a more striking proportion still is the large influx of adults from the provinces, which naturally keep up the rate of mortality.

CITY HORTICULTURE.—The Thames Embankment is already being made available for useful and ornamental purposes, for beyond the south-west corner of the Inner Temple gardens Mr. Broome is erecting a conservatory, now in a forward state of completion. These gardens will speedily possess a collection of beautiful green-house flowers on the very ground over which two months ago flowed the river.

Correspondence.

CITY HORTICULTURE.—**SIR,**—When I introduced the subject of city horticulture to the Society of Arts, in my paper on the evening of March 29th, it was with a feeling that it was one of considerable dimensions, far beyond what I was capable of treating fully myself, and that probably the most valuable result of my remarks would be the calling out from others of observations which might be more practical as well as suggestive than my own. Now, although the general interest of the subject was illustrated by the unexpected delivery of a lecture in Westminster, on the same evening, on a branch of the same subject, Window Gardening, by Mr. Bosanquet, which doubtless took away many of those who might have been present at the Society of Arts, and have added their remarks to those given in the discussion, yet, as it was, several new facts and points of interest as well as results of practice were added, evidencing, I think, how many people are thinking on the same subject; and this is further illustrated by the letter of Mr. Bridges Adams, in last Friday's *Journal*, on "Town Gardens," which I have read with great interest. I quite accept the feasibility of his plan of flat roofing; at the same time, in this variable climate, and so high in the air as on the tops of houses, I conceive that a glass covering would be very advantageous, not only for the sake of protection from smoke and the draught, which Mr. Broome spoke of as so injurious in the Temple gardens, but that thereby an additional living or workroom of large dimensions is obtained. I have the pleasure of fully accepting the remarks of Mr. Adams as regards the beauty of Paris and that of London, and how that of the latter might be enhanced by the individual taste of its citizens; and it is for reasons like this that it is so advantageous to have the opportunity of bringing the subject before the public through the medium of the Society of Arts. It is very evident that, not only in London, but in most of the great and increasing towns of this country, this love of horticulture is rife and active, and that, separately and individually, many have been practising different points of it, without being aware of what others have been doing, and without interchange of ideas and experience. For instance, I for one was not at all prepared for the fact, as given by Mr. Broome, that within his own area of assistance there were no fewer than twenty-four floricultural societies in different parts of London, each numbering from 100 to 120 members, who held exhibitions twice a year. I dare say this was a new fact to most of those who were present that evening. This had direct reference to flower shows, which form a very pleasing department of the subject, and one which can doubtless be carried, especially by intercommunication, far beyond its present condition. But I need hardly say that the subject of City Horticulture is one that goes far beyond mere flower shows; it is one that finds sympathy in the heart of English people without show, as indeed the remarks made by Mr. Philip Palmer, Mr. Bailey Denton, Mr. George Wilson, Mr. Sowerby, Mr. Slack, Mr. Wentworth Scott, Mr. Broome, and Sir Thomas Phillips all tended to show. These few words have been called forth by those of Mr. Bridges Adams of last Friday, and I am glad to find in him a fellow-labourer in the same subject; but before I saw them I had written a few lines in reference to "Orchards in Cheapside," as alluded to by Mr. Wilson in the discussion, and which I hope I shall not be taking up too much space by asking you to append to these.—In the discussion on Wednesday evening last, Mr. George Wilson alluded to an article which appeared in one of the periodicals two or three years ago, in which the author recommended the growing fruit trees on the roofs of houses in the heart of London. Those interested in the subject of city horticulture would, I think, be glad

to know the name of the periodical, and the date of the number which contained the article in question, and also whether the author had put in practice his suggestion, and if it was successful in the production of fruit. Leaves it is easy to produce. Flowers require an effort on the part of a plant, but fruit is the ultimate aim and success of its vitality. Mr. Slack's success was remarkable, in the production of such fine grapes in his glazed attic in Mount-street as he described on the same evening, and is most encouraging to those who, like myself, believe that the tops of houses in the metropolis and other large cities may be made pleasurable as well as useful, by one and the same means, that is by the use of glass instead of slate, and at no great increase of expense. An additional consideration may enter here, viz.: that by this means a portion of the enclosed contents of houses will be utilized, which often now are wasted, viz.: the pointed roofs, which are often shut off by a ceiling, and used for nothing, and are lost for any purpose, even that of ventilation; whereas, if used as suggested by Mr. Slack's experience, they would serve both for the purposes of ventilation and the growth of plants, flowers, and fruit trees. I confess also that I am anxious to hear what those who, in the habit of employing in numbers, such artificers as require the best light for their work, may think of the construction of such fully-lighted and well-ventilated work-rooms in the elevated situations proposed, above the denser strata of London fog; and I venture to ask you to put this question in your journal, in the hope of eliciting practical opinions on this point. Light is also known to be productive of health in human beings as well as in plants, &c. I believe there are data showing that the shady sides of large buildings, containing a large number of occupants, are not so healthy as those which are towards the sun, and thus enjoy a larger portion of light. Also, to put an extreme case, an attic is a more healthy place to live in than a cellar, and this I apprehend does not rest only on the pure air of the former, but also on its greater degree of light. Where the young, as in the case of milliners, flower-makers, embroiderers, &c., are employed in sedentary occupation, how far more healthy would they be if working in well-ventilated, airy, well-lighted rooms, with flowers growing round them, than in stifling close rooms, where the air and occupation together are so apt to lead to consumption! It appears to me that arrangements of this kind are highly favoured by the cheap rate at which glass can be now obtained. At no other period of the history of the world and of architecture could glass be obtained so cheap. And it does not appear that we have as yet by any means fully utilized this important advantage of having at our easy and economic command a material pervious to light and impervious to weather.—I am, &c.,
JOHN BELL.

GRANTS OF PROVISIONAL PROTECTION.

- Air, stoves for heating—650—R. Howson.
 Aeriform fluids, obtaining motive power from—827—M. P. W. Boulton.
 Almonds, machine for peeling—760—J. H. Wathew.
 Antiseptic fluids, apparatus for treating timber with—734—S. B. Boulton.
 Animal matter, preparing waste—893—W. M. Fuller.
 Apolite, method of treating—8—M. R. Leverson.
 Belle—3177—R. Wilson.
 Beer, composition for clarifying—799—W. B. Coleman.
 Bottles, protective labels for—853—W. Betts.
 Brushes—764—J. Vero.
 Candles, machines for cutting the tips of—874—J. L. Field.
 Candles, treating fatty matters for the manufacture of—817—R. A. Brooman.
 Cavaas, method of treating, &c.—752—W. M. Williams.
 Caustic liquor—829—T. Nicholson.
 Chains, ornamental metallic—843—E. Wolverson.
 Cloth, preparing—762—T. Kenyon, jun.
 Coal, apparatus for the distillation of—798—W. M. Williams.
 Compounds, preparing lubricating—867—W. West.
 Cotton gins—851—W. Richardson.
 Cotton, machines for preparing—786—T. Ogden.
 Deep water, apparatus for paying out telegraph cables in—825—R. Tidman.
 Designs, apparatus for indicating—815—D. Mackenzie.
 Fire-arms, breech-loading—711—R. A. Brooman.
 Fire-arms, breech-loading—772—J. T. Cook and J. T. Cook, jun.
 Fruit, machinery for dressing—502—D. Barr.
 Furnaces, apparatus for heating blast for—891—J. Player.
 Gas, carburetting—596—W. R. Bowditch.
 Grain, apparatus for thrashing—735—M. Meisel.
 Hand power, apparatus for propelling carriages by—798—W. Lane.
 Houses, apparatus for the protection of—819—C. F. Varley.
 Human body, apparatus for measuring the—635—J. H. Wilson.
 Hydrated oxide, preparation of—788—R. A. Brooman.
 Iron and steel, roiling—806—M. Morgans.
 Iron safes—459—J. Ferguson.

- Iron, machinery for working puddled balls of—779—W. Menclan.
 Japanned goods, ornamenting the surfaces of—831—T. Farmer and F. Lewis.
 Knives, &c., hardening—747—H. Wethered.
 Lace, manufacture of—716—J. Wilkie.
 Lamp, atmospheric pressure—562—W. B. Dalston.
 Light, apparatus for obtaining—841—G. F. Marchfield.
 Lighting and heating, materials for—865—W. Clark.
 Machinery, file cutting—885—W. Brookes.
 Metals, machine for rolling—736—J. Ramsbottom.
 Motive power—802—V. Baker.
 Motive power engines—651—W. Clark.
 Oars—161—E. D. Faroot.
 Oil feeders—859—J. Buckingham.
 Pasteboard, apparatus for cutting—789—W. Clark.
 Penell shield—746—C. A. Wheeler.
 Piano, &c., proper action of the hands of players upon the—655—W. T. Hamilton.
 Pins, fastenings for—881—J. L. Pulvermacher.
 Potatoes, &c., implement for paring—887—C. Burditt.
 Railway trains, communication between passengers and guard of—839—J. C. Stovin.
 Railways, permanent way of—738—W. Loader.
 Ranges, construction of kitchen—875—F. Thomas.
 Reflectors—288—A. B. Stocker.
 Roads, locomotive engine and carriages for common—700—A. L. Mackenzie.
 Safes, locks for—778—S. Chatwood.
 Scarves—773—M. Eley.
 Screws, apparatus for cutting the threads of—835—J. Green.
 Sea weed, preparation of—877—R. Young and C. F. O. Giamford.
 Sewing machines—766—O. Robinson.
 Sewing machinery—776—A. V. Newton.
 Sewing machines—883—W. N. Wilson.
 Sewers, &c., apparatus for ascertaining the state of—848—R. W. Barnes.
 Ships, cabin furniture for—829—C. Bevan.
 Signals, working railway—740—R. Bell.
 Spatter dashes, method of closing—658—E. Carchon.
 Spindles, &c., apparatus for lubricating—782—J. W. Midgley.
 Stamping, apparatus for—865—G. Bishop.
 Steam, increasing the mechanical value of—745—B. Lawrence.
 Steel, casting ingots of—861—C. J. L. Lefter.
 Sulphurous acid, obtaining—729—A. P. Price.
 Telegraph wires, posts for—749—G. Dibley and F. Braby.
 Traction engines—863—J. Buckshaw and W. S. Underhill.
 Turpentines, preparation of—870—J. E. G. and C. H. Freeman.
 Ventilating blinds—879—H. W. King.
 Vessels, compositions for coating—871—J. C. C. Halkett.
 Vessels, machinery for the propulsion of—3179—J. and J. H. Fothergill.
 Warps, apparatus for drying—860—R. Holroyd and J. H. Bolton.
 Washing, machine for—837—J. A. Swaney.
 Weaving, looms for—845—J. Milton.
 Weaving, looms for—750—J. Bullough.
 Weighing machines—757—J. McConnell.
 Wheel gearing—744—J. Standfield.
 Wool, apparatus for combing—622—S. and W. Smith.
 Wool, apparatus for washing—808—G. E. Donisthorpe.
 Yarns, method of treating—490—J. Mallison.
 Yarn, manufacture of—774—J. Philippenthal.
 Yards, construction of ships—873—T. Glover, jun.
 Zinc, machine for cutting sheets of—662—R. G. Fisher.

INVENTION WITH COMPLETE SPECIFICATION FILED.

- Iron rods, manufacture of—912—H. A. Bonneville.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

APRIL 26.—"On the Wear and Tear of Steam-Boilers."
By F. A. PAGET, Esq.

MAY 3.—"On Colonization; its Aspects and Results."
By WILLIAM STONES, Esq.

CANTOR LECTURES.

The Third Course for the present Session, consisting of six Lectures, "On Some of the Most important Chemical Discoveries made within the last Two Years," by Dr. F. GRACE CALVERT, F.R.S., F.O.S. (Corresponding Member of the Royal Academy of Turin; of the Société Industrielle de Mulhouse; of the Société Impériale de Pharmacie de Paris, &c.), is now being delivered on Tuesday evenings, at Eight o'clock, as follows:—

APRIL 25TH.—LECTURE 3.—On the Discoveries in Agricultural Chemistry.

MAY 2ND.—LECTURE 4.—On the Discoveries in Physiological Chemistry.

MAY 9TH.—LECTURE 5.—On the Discoveries in the Chemistry of Rocks and Minerals.

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

INSTITUTION.

The following Institution has been received into Union since the last announcement:—

St. Helen's (Lancashire) Mechanics' Institution.

Proceedings of the Society.

NINETEENTH ORDINARY MEETING.

Wednesday, April 19, 1865; Professor Robert Bentley, Member of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Balforn, John Edward, 6, The Lawn, Shepherds'-bush, W.
Bedder, William, Saltash, Cornwall.
Borochitzky, J. F., 32, Tavistock-place, W.C.
Botly, William, Salisbury Villa, Upper Norwood, S.
Buckley, R. S., Moseley, by Manchester.
Clever, Joseph, 7, Coleman-street, E.C.
Cozens, Samuel E., Phoenix Wharf, Southwark, S.E.
Davison, Thomas Langmore, 2, Lavender-terrace, Lavender-hill, S.W.
Edwards, Samuel, 13, Limes-grove, Lewisham, S.E.
Green, John, 2, Gloucester-place, Lower Tulse-hill, S.
Hawke, John, 3, Brockley-villas, Brockley-road, Newcross, S.E.
McClellan, Samuel, 7, Cambridge-terrace, Upper Lewisham-road, S.E.
Shanks, James, St. Helen's, Lancashire.
Skelton, John, jun., M.D., 105, Great Russell-street, W.C.
Taplin, Thomas, 14, St. James's-square, S.W.
Westhead, Albert, 20, George-street, Hanover-square, W.
Westhead, Edwd. S., 20, George-street, Hanover-sq., W.
Wilkinson, T. L., 1, York-villas, Sydenham-park, S.E.
Wynne, F. Osborne, Archcliffe-street, Dover.

The following candidates were balloted for and duly elected members of the Society:—

Austin, Charles E., 7, Broad-sanctuary, S.W.
Bradley, E. B., 1, Church-meadows, Sydenham, S.E.
Brown, George, Bruckwood-house, Croydon, S.
Buckney, Thomas, 12, Brunswick-square, Camberwell, S.
Canning, L., Abbey-wood, S.E.
Chambers, W. Oldham, Lowestoft.
Cooke, Rev. John Hunt, Elm-grove, Southsea.
Costeker, John, St. John's-hill, Wandsworth, S.W.
Da Silva, Johnson, Burntwood, Wandsworth-common, S.W.
Laslett, Thomas, Devon-house, Maryon-road, Charlton, S.E.
Lewin, William Henry, 135, Southampton-street, Camberwell, S.
Lloyd, Percy, Ash-villa, Burnt-ash-lane, Lee, S.E.
Lucas, Charles, 9, Louvaine-road, St. John's-hill, Wandsworth-common, S.W.
Massey, Hugh H., 33, Camberwell-green, S.
McArthur, Alexander, Raleigh-hall, Brixton-rise, S.
McEwan, James, 38, Cannon-street, E.C.
Nagle, Rev. W., 1, Blackheath-villas, Blackheath, S.E.
Parker, Thomas, 10, Brunswick-square, Camberwell, S.

The Paper read was—

ON THE PRESERVATION OF NATURAL HISTORY SPECIMENS FOR MUSEUM PURPOSES.

By B. WATERHOUSE HAWKINS, Esq., F.G.S.

Museums have during the last 25 years become so important an element of civilization and education that they form a subject for discussion quite within the true province of the Society of Arts, and the first question I would suggest is—Do the natural history specimens in their present state fulfil their purpose of teaching, and of assisting the public to appreciate the advantages of a knowledge of natural history in any proportion to the vast cost of their collection and preservation?

The late Prof. Edward Forbes, in a valuable pamphlet on the uses of museums, says—"It is to the development of provincial museums that we must look in future for the extension of intellectual pursuits throughout the land." He then goes on to say, "When a naturalist goes from one country to another his first inquiry is for local collections. He is anxious to see authentic and full cabinets of the productions of the region he is visiting, and, if possible, to study them apart and not mingled with general or miscellaneous collections."

"For general affinities of objects that concern the whole world he seeks the great national collections, such as the British Museum, the Jardin des Plantes, and the Royal Museums of Berlin and Vienna, but that which relates to the particular locality he is endeavouring to become acquainted with, he expects to find either in a special department of the National Museum or in a separate establishment, the purpose of which is, in a scientific sense, patriotic and limited. In like manner, when the inquirer goes from one province to another he seeks first for local collections. In almost every town of any size or consequence he finds a public museum, but how seldom does he find any part of that museum devoted to the illustration of the productions of the district. The very feature which of all others would give interest and value to the collection, which would render it most useful for teaching purposes, has in most instances been omitted or so treated as to be altogether useless."

The public attention is now so much occupied with fish culture, not merely in the natural history sense, but also for economic purposes, as an article of food, and of commerce, and, therefore, legitimately within the scope of the direct action of the Society of Arts, that I need not give any other reason for commencing with this portion of my subject—the preservation of fish specimens.

The animal kingdom is divided into two great classes, the invertebrate, comprising the molluscs, the radiata, and articulata, of which I do not intend to speak—and the vertebrata, commonly known as birds, beasts, and fishes, which will form the subject of my remarks. This is, however, not a lecture on natural history, and I need not, therefore, enter into a description of the construction of the vertebrata, except to point out the fact that they have bony frames, to which muscles and tendons are attached.

Anglers and others interested in fish have often applied to our museums to see a complete collection of preserved specimens, but even at the British Museum, which is first in cost to the nation, first in size, and first in the vastness of the number of specimens it contains, such a collection of fish is not to be seen by the public. There are two modes of preserving fish: in spirit in bottles, and by dried skins fastened to a slab, or the whole stuffed in the true sense of the word; to which, colour, varnish, and glass eyes are added to complete the life-like aspect of the "fish out of water." Neither of these processes gives much idea of the appearance of the fish while living, and specimens thus preserved are not of so much use in a natural history point of view as a skeleton of the fish would be.

In the spirit bottle the whole of the fish is preserved;

but this method has many disadvantages, which render it useless as regards the general public. What is required for them is a collection in which they can, at a glance, see the various differences between herring and pilchard, char and salmon, &c., and become acquainted with the modifications of form peculiar to the various kinds of fish.

One disadvantage is that the convexity of the sides of the spirit bottles deforms the objects seen through them, so that specimens preserved in this manner are only of use to the naturalist, who removes them from the bottles for the purpose of minute examination. To obviate this I propose that flat-sided glass cases or boxes should be used. Experiments were at one time made with flat sided glass cases at the Museum of the College of Surgeons, and at the British Museum, but these failed to be satisfactory; the fluid used was Goadby's solution (spirit being then too expensive even for our national collection), which expands with every variation of temperature, and it was found impracticable to seal the cases so hermetically as to prevent the solution from oozing through the crevices, and not only producing an unsightly appearance and destroying other specimens, but also admitting the air to the specimens in the case.

I have lately seen a slate frame, of a very simple construction, invented by a talented engineer, which is held together by iron bolts, in the same manner as a slate cistern, and which would, when fitted with plate glass sides, form a hermetically sealed case, in which the specimens of fish could be admirably displayed. These cases could be erected as a double screen, each being of about 9 inches, or the whole 18 inches in width, just wide enough to contain the body of the fish, and thus occupying a smaller amount of space, and giving a better view of the specimens than has yet been afforded by any other method. The specimens in bottles would still be retained for the use of the naturalist, and thus both requirements, the instruction of the general public and the inquiries of the scientific man, would be satisfactorily met. The remarks and suggestions which I have made with reference to fish apply equally to all other animals living under water and to reptiles.

Of all the classes of animal preserved in museums, the most successful, or rather the least objectionable in appearance, have always been the birds. The exact arrangement of the feathers of birds preserves the natural appearance, even if the skin be supported merely by a wire frame; but such specimens generate the destructive moth, to the detriment of the rest of the museum collection. This modification of my praise of preserved birds must not be applied to the specimens prepared by Mr. Gould, Mr. John Hancock, or Mr. Charles Waterton, who possess no ordinary amount of artistic power as well as being eminent naturalists. In the Great Exhibition of 1861 a large field was opened to the taxidermist. In the Sardinian department there was "a remarkable specimen. It exhibited to perfection the art of representing the living animal, not only in its general form and character, but marking also the fine and delicate undulations of the flesh and muscles, and all the anatomical details which are externally traceable. The difficulty of effecting this is so great, that generally it is scarcely attempted, but in this instance the artist had been most successful. The process adopted by Sig. Comba, the exhibitor of this specimen, has been that of modelling the animal in clay, and from that model forming a mould. This mould enabled him to construct a figure of a material resembling papier-mâché, retaining all the fidelity of the original model. Upon this figure the skin was stretched." Besides this artistic specimen, which obtained a prize medal, there was a collection exhibited in 1861 by Plouquet, of Wurtemberg, consisting of a "series of scenes taken from Kaubach's illustrations of the well-known German story of 'Reynard the Fox,' and executed with great skill, expression being thrown not only into the attitudes, but even into the countenances of the animals." The skins of some of the larger specimens exhi-

bited by M. Plouquet were stretched over plaster models. Mr. Bartlett's specimens of birds obtained a prize medal in 1851, as also those exhibited in 1862 by him and his pupil, Mr. F. W. Wilson. Mr. John Hancock exhibited several single specimens and groups of birds and animals in 1851 which were "most truthful as to the representation of the habits and appearance of those creatures, and in every respect of the highest merit," and obtained a prize medal.

We have seen, then, that papier maché was adopted for that admirable model of the elk, from Turin, sent to the Exhibition of 1851, by Sig. Combà, which so justly received the medal. I have a vivid recollection of the beauty of that work, and am confident that the process by which it was produced might be safely adopted for all the models that may be required henceforth in our museums; indeed, I can state that successful experiments, in the use of papier maché, have been made by Mr. Bartlett's pupil, Mr. Wilson, at the Crystal Palace, the lightness and plastic nature of the material affording many facilities for the reproduction of the true form. Its cleanliness also adds much to its value, and the facilities for attaching the skin to the concavities by means of any of the cold liquid glues now in use, render the paper model the most hopeful means for the improvement of taxidermy that has yet been suggested. In the large group of stag and dogs, exhibited in 1851, and afterwards in the possession of the Crystal Palace Company, some of the skins were stretched over plaster of Paris casts, taken from the body of the animal immediately after the removal of the skin, but this material is too heavy and brittle for general use.

If, then, the majority of our museum specimens are not at present good, how can they be made better for the future? The preservation of animal forms is one of the most ancient arts still practised. Its most primitive form was the embalming of the dead bodies without removing the internal parts. The Greeks and Romans adopted the still more crude method of dipping the body in melted wax, which disguised the form. These preparations were made in Egypt, Greece, and Rome by the priests who collected them in the temples, but the idea of a museum of natural history originated in Italy, and it was the collection of an Italian amateur of this science, which, after several changes of hands, formed the nucleus of our British Museum. 'Thou'gh to the question, "What's in a name," there is a stereotyped answer, about a roe by any other name, &c., I believe that the first step towards improving the character of our museum specimens would be for the taxidermist to recast his name, and drop the title of "stuffer," "bird stuffer," and "beast stuffer," which suggests only a kind of natural history upholstery, little above the stuffing of a chair cushion. If he adopted some more elevated title, a higher class of work would be expected of him, his specimens would be subjected to artistic criticism, and a higher price would be paid for them; we should thus obtain ten good well preserved specimens of typical natural forms for every twenty or thirty of the ill-looking grotesques that are now so closely packed in the costly plate-glass cases of the British and other Museums.

By "well-preserved specimens" should be understood well modelled restorations of the animal's real form as in life, in a quiet attitude, at which the spectator could gaze contentedly for some minutes without that feeling of impatience for the creature to move which is excited by beholding an animal set up in the action of a spring or leap, which in life it could only maintain for a moment of time.

The production of well-preserved specimens of this standard is not so easy a task as may be supposed by the inexperienced spectator. It is easy to condemn a stuffed animal as unlike the living thing, while others suppose that it cannot be wrong because it is the thing itself. The actual skin (say they) and the greater part of the bones, are there, and, consequently, it only requires a little tow or other yielding material to be put between the bones

and the skin to replace the flesh, the size of the skin being the gauge or measure of the quantity. The skin is carefully and closely sewed up when full. This is the operation of stuffing, as it has been practised for many years.

The difficulties which the stuffer has to contend with are tolerably evident in specimens now exhibited. These skins of deer, antelopes, and the wild ass from Persia are a very fair average of the state in which the best skins are received from abroad—hard, shrunk in every direction, contradictory of the original form of the animal, sometimes preserved by applying turmeric, sometimes tanned, yet stiff and unmanageable, like some of the other specimens present. The stuffer has to cleanse and soften the skin as the preliminary step to his future operations; then, having made out the species or its affinities, he has to make his measurements very carefully, with considerable deductions and allowances for the stretching of the skin in the direction in which it may have been hastily pulled from the body of the animal; this hasty method of skinning the animal has generally the effect of elongating the skin in one direction, viz., the length of the animal, while of course the width or circumference of the body is disproportionately reduced, as the exhibited examples will demonstrate. It will therefore be seen, that the stuffer has to remedy deformities before he can construct the hard frame work that is to unite with the bones already there, being left in the skin, as the thigh, the tibia, and tarsal, with the metatarsals that constitute the bones of the foot, or he may have to make an entire frame or substitute for the skeleton, upon which he must place the rest of his model, having the numerous convexities and concavities that shall faithfully represent the bulk of the muscles and sinews covering the bones of the animal as he appeared in life. This is but preliminary; he has then to make the skin fit his model in every part, or perhaps it would be more correct to say that he has to make his model fit every part of the skin, in spite of the deformities contracted in the first act of skinning, whereby it has been both stretched and shrunk, while the latter effect has been increased to an almost unlimited extent, by the drying process that commenced suddenly in the tropics, and has been continued during a long voyage.

The eye was formerly treated as a mere glass button, without any regard whatever to true imitation of that organ itself, either in colour, form, or expression. In 1848 I was induced to take up the subject, and at my suggestion eyes of an improved character were formed of glass, which enabled the artist, by means of painting and the use of various coloured silks and a backing of velvet, to produce an artificial eye which should accurately imitate the real eye of the animal. These eyes are now getting into general use, for I did not patent the invention, and they are very cheap. Formerly the only good artificial eyes were to be had in Belgium, and were very dear, costing frequently as much as £2 for a single pair of eyes, and even then it was not in the power of the stuffer to adapt them specially to the subject in hand.

With such materials and opposing difficulties, I maintain that the stuffer of birds and beasts ought to be something more than a stuffer, for he has a more arduous task than the sculptors' modeller, who imitates the external form of a living animal, with more or less knowledge of the internal anatomy or framework. If, then, the stuffer's work is to be expected to bear comparison with the work of the artist modeller, the many greater disadvantages that the stuffer has to contend with, and the ingenuity he must possess to conquer them, should be taken into account, and, as greater skill and better education are required, a higher remuneration and rank should be accorded to the artistic workman who shall at all times prove himself competent to adapt the distorted skin to a correct artificial model, possessing the true form of the animal so preserved. Whenever this style of preserving specimens of natural

history can be accomplished for museum purposes we may then contentedly forego the motley crowd that now fills the costly glass cases at our national museum and unprofitably occupies the valuable space of those large rooms, pronounced insufficient for the continuous influx of stuffed specimens, but which might be large enough for well-selected typical forms, having the real skin put upon a life-like model, side by side with a type skeleton of the group, from which the artist, sculptor, or painter could derive instruction sufficient to qualify him to continue his studies from the living animals belonging to the Zoological Society, who, in their liberal wisdom, have always allowed artists free access to their collection. Then we should have our art-students in possession of the same facilities for the study of animal forms as are possessed by the student of high art. The museums containing true models of various animals, in lieu of the present style of stuffed specimens, would be to the animal painter the equivalent of the casts from the antique, to educate him gradually to take advantage of the animal life academy always to be found at the Zoological Gardens.

DISCUSSION.

Mr. G. F. WILSON, F.R.S., said Mr. Hawkins, in his very interesting paper, had spoken of the preservation of specimens of fish. Ten years ago he (Mr. Wilson) tried a great many experiments with what was then a new medium, viz., glycerine. He tried the effect of this on a large lake trout, which he caught in Scotland, and enveloped in a cloth saturated with glycerine, in which it was kept in a good state of preservation. It was afterwards presented to Prof. Owen, and placed among the objects of this character in the museum of the College of Surgeons. He had understood that the same medium had been used by Dr. Carpenter for the preservation of star-fish. He should be glad to hear Mr. Hawkins's opinion as to the advantages or disadvantages of the use of glycerine for the preservation of this class of object.

Mr. GEORGE WHITE said the subject which had been brought before them in so interesting a manner naturally suggested the inquiry how museums might be made educationally valuable. The wants of the scientific inquirer and of the artist had been more or less considered in our museums of natural history; but there was one point to which the prominence it deserved had not been given—that was the general educational uses of these establishments. They had heard this evening that the British Museum was not so largely visited by the public as was formerly the case. He was not at all surprised at that fact. As the natural history specimens there got dingy and dusty, and as people came to know more about them, and as, moreover, they could often see better specimens in other museums, it was not surprising that our great national collection was not attended by such large numbers as was the case some years ago. Mr. Hawkins had made the remark that there was no class of specimen in which they had succeeded so well as in birds; with great deference he thought they were amongst the most unsuccessful portions of the museum. When a boy he (Mr. White), like most others in the country, amused himself a great deal in searching the hedge-rows for birds' nests, and acquired a large collection of eggs; he also practised to some extent as an amateur taxidermist, and it was a great prize to him when he alighted upon a book on that subject. He then gratified his tastes by preparing specimens of the birds of the locality in which he resided, and it was not till he was a young man that he visited the British Museum. When he first went there he must say he was disappointed with a great number of things he saw. He was recommended to go again, and to confine his attention to one particular class of object to which his tastes inclined. At that time there were scarcely any birds' eggs in the museum, and with regard to the birds themselves, he put the question to himself, "Do all birds sit upon sticks in one unvarying

attitude? and are they all constantly sitting with their wings closed, and their bills pointed in one direction?" He was surprised to see whole regiments of water wag-tails, tom-tits, and yellow-hammers, set in rows above each other, all exactly alike; and he could learn no more from looking at twenty or thirty than he could from looking at one. Then he was struck with the thought, "How little all this exhibition teaches me." At the time he spoke of there was no classification of the birds, and the labelling was extremely imperfect. An alteration had taken place in that respect, but very great improvements were still required. Instead of having thousands of birds stuffed, as a cook might do for roasting, he would have them in fewer numbers, well classified and labelled, and placed in natural postures. These might be varied to a great extent. For instance, the birds might be represented as flying to and from their nests, giving food to their young, &c. He had seen nothing which had given him satisfaction in this respect since the Exhibition of 1851, and in comparison with 1862 he decidedly gave the palm to 1851. The expression and attitudes of the birds and animals shown there were Landseer-like, and all the features of life were admirably preserved. On this subject he believed a great work might be undertaken by this Society by the exercise of its influence to render museums of national history more educationally interesting and entertaining to the masses who visited them.

Mr. J. BEAVINGTON ATKINSON had not intended to make any remarks on the subject treated by Mr. Hawkins in his most interesting and instructive paper, but he had been induced to rise because a point had been raised in it which had involved a subject in which he had long felt special interest—that of art and the connection which existed between science and art. The points to which they had had their attention directed were of great practical importance, and the few remarks he should make would have relation to that part of the subject with which he was more particularly concerned. It was related in the life of Haydon, the painter, that he and his pupil, Sir Edwin Landseer, made a careful dissection of a lion, as a necessary part of the education of an artist, showing, as had been pointed out by Mr. Hawkins, how strongly these distinguished men felt that a thoroughly educated artist had something more to do than to attend merely to the gloss on the skin or the texture of the hair, and must necessarily study the anatomy of the animals which he painted. Some of the marbles in the Vatican afforded the strongest evidence that artists in ancient times paid attention not merely to the superficial texture of the skin, but to the accurate configuration of the body of the animal represented. Coming down to the present time, he might call attention to a recent work on the camel,* by Elijah Walton, which was the result of really diligent and careful study of the animal, and the value of which to artists and students of natural history could hardly be overrated. The artistic advantages of really correct drawings of this animal had been recognised by artists and critics. Many of the drawings of the late distinguished artist David Roberts possessed, no doubt, very high merit, but when he attempted the delineation of the camel, he failed to show that accurate knowledge of the anatomy of the animal which was manifest in the works of another great artist, Lewis. The art value of the drawings of the latter was immeasurably greater, simply because he understood the structure of the camel. He might further refer to a painting which they would see at the forthcoming exhibition of the Royal Academy, by Frederick Goodall, R.A., the subject being, "A Flood upon the Nile." In that painting they would see an accurate delineation of the camel—a most difficult animal to draw, because, although pronounced in its articulations, yet in its movements most loose

* "The Camel; its Anatomy, Proportions and Paces." By Elijah Walton. (Day and Son.)

and undecided. There was this obvious connection between the study of anatomy and art, so that a picture might in fact be looked upon as a work of science as well as of art. He thought what they had heard this evening enforced a truth which they were more and more ready to admit—that the highest science was the best and truest art; and that in accuracy of detail, which in previous years had been considered to belong only to the man of science, would the artist find his highest beauty.

The CHAIRMAN said it was now his pleasing duty to propose that the thanks of the meeting be given to Mr. Hawkins for his paper, which he had no hesitation in characterising as one most interesting and instructive, and he trusted it would lead to valuable results. Having been a pupil of the late Professor Forbes, he well recollected his crushing denunciations of the different museums he found in passing through the country, and his regret that these local establishments could not be made strictly educational, more particularly as illustrating the natural history of the locality, a view advocated by Mr. Hawkins this evening. No doubt the great difficulty in all museums had been the fact of the inartistic way in which the natural history specimens had been preserved, in no degree resembling the animal itself, or the form of any living object whatever; but if these objects were placed before them in a really satisfactory form, as might undoubtedly be done, though it would require a great deal of time and skill to do it, the museums would be more frequented than they were at present, and would be more valuable in an educational point of view. With regard to the statement that the numbers visiting the British Museum had very materially diminished, it was to be borne in mind that some few years ago it was the only exhibition of its kind in the country; whereas now there were the collections at South Kensington, the Crystal Palace, and elsewhere. Moreover, when they saw such inartistic specimens as that exhibited this evening as a fair type of what was to be met with in the national collection of zoology, it was not to be wondered at that, with the improved taste of the age, such a collection should lose its attractions. He regretted that the subject before them was one on which he had but little practical knowledge, his own department being more especially the vegetable kingdom. Hitherto the miserable dried specimens of plants usually seen were of little value to the scientific man; to those who desired to know what the plant really was they conveyed no idea. He was happy to find that a great improvement in this respect was to be looked for, owing to the modifications introduced by Mr. Ward, the well-known inventor of the Wardian case. His idea was to arrange the entire vegetation of a particular mountain or district in such a manner as to be valuable to the man of science as well as gratifying to the general visitor. Specimens either of the animal or vegetable kingdom, had no value unless they gave some correct notion of what the objects represented really were in their natural state. He should have been glad to have heard some further discussion with respect to preservative substances. He agreed with Mr. Hawkins that Goadby's solution was not satisfactory, and the only reason it was formerly used was on account of the great expense of spirits. He believed methylated spirit, with three parts of water, was the best liquid that could be employed; while for vegetables and plants, salt and water, vinegar and water, or dilute pyroligneous acid, answered well, one special advantage being that they preserved the colour. He was sure the meeting would unanimously agree that their thanks were eminently due

Mr. Hawkins for his paper, and for the peculiarly clear and artistic manner in which he had illustrated his subject on the black canvas.

The vote of thanks having been passed,

Mr. WATERHOUSE HAWKINS, in acknowledging the compliment, expressed his regret that in our National Museum the intending emigrant and colonist sought in

vain for properly classified specimens of the animals, birds, &c., to be found in the new country to which he was going. He thought the Society might assist in obtaining something like a geographical arrangement of this kind, showing, even if only on a small scale, the animals of New Zealand, Australia, &c. Such an exhibition would be of great value to those going out as emigrants or as collectors, and would prevent the latter sending home useless things for want of that knowledge which might be obtained in a well-organised museum.

Mr. Hawkins illustrated the various points of his paper by sketches in chalk on the black board, and exhibited a collection of stuffed animals showing defective as well as meritorious work of this kind.

DUBLIN INTERNATIONAL EXHIBITION.

The interior of the building now begins to present a very busy aspect, the works of the contractor in painting, decorating, glazing, &c., being completed, and gas-pipes having been laid throughout the building; the business of the exhibitors has begun in earnest, in fitting up cases and arranging counters, goods, &c. The court in the Indian gallery has been railed in preparatory to the work of fixing cases and opening packages. In the Colonial gallery the courts and counters are all up, and we see packages from Canada, Nova Scotia, Mauritius, Natal, Jamaica, West Africa, Falkland Isles, Ceylon, Queensland, Siam, &c., waiting to be opened.

Among the commissioners, &c., already present or on their way are Mr. James Morris, representing Mauritius; Dr. Forbes Watson, India; Mr. Tyndal Bright, Victoria; Rev. Dr. Honeyman, Nova Scotia; Mr. A. Ferro, Malta; and Mr. W. Hewitt, China and Japan.

The preparations for the due reception of His Royal Highness the Prince of Wales, who will stay with Lord Wodehouse, are progressing rapidly. The musical performances at the opening on the 9th of May, with nearly 1,000 voices, will be very effective. A grand ball will be held in the building on the 12th, to which only season-ticket holders and members of the Musical Society with which it originates will be admitted. The Grand Lodge of Ireland also proposes to give a masonic ball if the Prince remains long enough. The grounds of the Palace are already beginning to wear a more finished aspect, consequent on the fine weather; and conservatories, blocks of coals, obelisks, fountains, and other objects for which room cannot be found within the building are to be accommodated there.

Work has commenced in the foreign courts. M. Corbière, the representative for France, has already got his court in preparation in the centre of the building. Germany, Italy, and other states are also at work, their goods having arrived. The picture galleries begin to wear an attractive aspect.

The Queen of Spain has named six gentlemen as Royal Commissioners for that country; and about fifty pictures from the National Gallery at Madrid are on their way to Dublin.

It has been determined that the jurors for the several classes shall be selected by the Executive Committee from the recommendations of the several committees and representatives of foreign countries, and in accordance with the wishes of the exhibitors. This mode of selection has been considered preferable to the direct election by the exhibitors, of whom it is not to be expected that a large proportion will be present in Dublin at one time; the difficulty of collecting their suffrages, and of obtaining anything like agreement among them, where there was no opportunity for previous meeting or consultation, was sufficiently apparent in 1862; and the unsatisfactory results of the system then adopted have induced the Committee to assume the responsibility of nominating the jurors, taking care to consult the wishes of the exhibitors, and to seek for the assistance of the most competent men in

every department of science and manufactures, both at home and abroad. With this view the several foreign committees have been requested to submit the names of such of their countrymen as they would recommend for the office, and who are likely to visit Dublin for the purpose of performing the duty. The design for the medal is by the celebrated medallist, William Geefs, of Brussels. It is a handsome composition, representing the Spirit of Progress in Arts and Manufactures enriching Ireland from a full cornucopia, while a view of the building in the background and various emblems of industry mark the year as an epoch in the improvement of the country.

The leading railways have already conceded a reduction of 25 per cent. on the ordinary return fares, and it is hoped will yet run cheap excursion trains to induce numbers to visit the Exhibition and the lovely lake scenery of Ireland in the autumn. The city is painting and putting on its brightest aspect for the occasion, and a register of the charges for lodging and hotel accommodation has been established at the inquiry office in the building. The steam packet companies have reduced the charges considerably on goods intended for the Exhibition. The Royal Dublin Society has conceded the use of its premises for such agricultural implements and goods as cannot be accommodated in the Exhibition building; and altogether the arrangements thus far promise a very great success for this second International Exhibition originated in Ireland.

THE SEWAGE OF TOWNS.

The Sewage Commission, consisting of the Earl of Essex, Professor Way, Messrs. Robert Rawlinson, J. Bennet Lawes, and John Simon, have just issued their report, which states that since the date of the last report (August, 1861) the commissioners have, through a committee, consisting of Mr. Lawes and Professor Way, continued at Rugby the experiments which were undertaken in 1861 on the application of sewage to land. These experiments have not been confined to the application of sewage in different quantities to land, but have extended to the consumption, by cattle, of the produce so obtained, and to the production of meat and milk, and have been accompanied by a careful record of the quantities and market value of the products, and by numerous analyses of the sewage before and after irrigation, as also of the grass and of the milk. The general conclusions are summed up as follows:—1. The right way to dispose of town sewage is to apply it continuously to land, and it is only by such application that the pollution of rivers can be avoided. 2. The financial results of a continuous application of sewage to land differ under different local circumstances; first, because in some places irrigation can be effected by gravity, while in other places more or less pumping must be employed; secondly, because heavy soils (which in given localities may alone be available for the purpose) are less fit than light soils for continuous irrigation by sewage. 3. Where local circumstances are favourable, and undue expenditure is avoided, towns may derive profit, more or less considerable, from applying their sewage in agriculture. Under opposite circumstances, there may not be a balance of profit; but even in such cases a rate in aid, required to cover any loss, need not be of a large amount. On the basis of the above conclusions, the Commissioners submit that the following two principles are established for legislative application:—First, that wherever rivers are polluted by a discharge of town sewage into them, the towns may reasonably be required to desist from causing that public nuisance. Second, that where town populations are injured or endangered in health by a retention of cesspool matter among them, the towns may reasonably be required to provide a system of sewers for its removal. And should the law, as it stands, be found insufficient to enable towns to take land for sewage application, it would, in the opinion of the Commission, be expedient that the legislature should give them powers for that purpose.

ON THE ACTION OF SEA WATER UPON CERTAIN METALS AND ALLOYS.

By F. CRACE CALVERT, Ph.D., F.R.S., F.C.S., &c., AND RICHARD JOHNSON, F.C.S.

We were induced to examine the action exerted by sea water, in consequence of the rapid changes which have taken place of late years in naval architecture, and especially in the substitution of metals and alloys for wood, and because one of us is largely engaged in the manufacture of wire for submarine and other telegraphs, and, when spun into ropes, for ships' rigging.

To carry out the above views, we took 20 square centimetres of each metal, which we cleaned with great care and attention, in order that the action of the sea water might have its full effect; then two plates of each metal were placed in separate glass vessels, and immersed in equal volumes of sea water. After one month the plates were taken out, and any compounds that had adhered to the surface carefully removed; the plates were then dried and re-weighed, and the loss estimated. To render our results of more practical value, we have calculated the action of 100 litres of sea water upon one square metre of each metal, and the following are the amounts of metal dissolved:—

	Grammes.
Steel	29.16
Iron	27.37
Copper (best selected)	12.96
Copper (rough cake)	13.85
Zinc	5.66
Galvanised Iron (Johnson's process)	1.12
Block Tin	1.45
Stream Tin	1.45
Lead (virgin)	Trace
„ (common)	Trace

These results lead to the following conclusions:—

1. That steel is the metal which suffers most from the action of sea water.

2. That iron is most materially preserved from the action of sea water when coated with zinc, and, therefore, not only should iron exposed to the action of sea water be galvanised whenever this is practicable, but, in our opinion, it would amply repay shipbuilders to use galvanised iron as a substitute for that metal itself.

The above facts perfectly confirm those which we have already published in our paper, "On Galvanised Iron for Armour Plated Ships," in which it was shown, that when iron was in contact with oak they mutually acted upon each other, producing a rapid destruction of the two materials, whilst little or no action took place between galvanised iron and the wood.

3. The extraordinary resistance which lead offers to the action of sea water, naturally suggests its use as a preservative to iron vessels against the destructive action of that element; and although we are aware that pure lead is too soft to withstand the wear and tear which ships' bottoms are subjected to, still we think that an alloy of lead could be produced which would meet the requirements of shipbuilders.

Feeling that experiments made with a limited amount of sea water might not be a fair criterion of the action of the ocean upon metals, we repeated our experiments upon plates of 40 centimetres square, which were immersed for one month in the sea on the western coast (Fleetwood), taking the precaution that they should be constantly beneath the surface of the water, and suspended by flax rope attached to a wooden structure, to prevent any galvanic action taking place between the plates and the structure to which they were attached.

The following are the amounts of metals dissolved:—

	Grammes.
Steel	106.31
Iron	99.30
Copper (best selected)	29.72
Zinc	34.34
Galvanised Iron (Johnson's process)	14.43
Lead (virgin)	25.63
„ (common)	25.86

The foregoing figures suggest the following remarks:—

That the action has been much more intense, in this instance, than when the metals were placed in a limited amount of water at the laboratory. These results are due probably to several causes acting at the same time, viz.:—that the metal was exposed to the constantly renewing surface of an active agent; and that there was also a considerable friction exerted on the surface of the plate by the constant motion of the water, there being at Fleetwood a powerful tide and rough seas. What substantiates this opinion is, that the lead plates undoubtedly lost the greater part of the weight, not by the solvent action of the sea water, but from particles of lead detached from them, in consequence of their coming in contact with sand and the wooden supports to which they were attached; but this cause of destruction having been observed with lead plates, it was afterwards carefully guarded against in the case of all the other metal plates.

We also deemed it desirable to examine the action of sea water on various brasses. We therefore immersed for one month plates of various alloys in that fluid, and proceeded to record our results:—

ACTION OF 200 LITRES OF SEA WATER UPON ONE SQUARE METRE SURFACE OF THE FOLLOWING BRASSES:

Composition of the Brasses.	Quantity of Metals Dissolved.			
	IRON.	COPPER.	ZINC.	TOTAL.
Pure Copper 50				
Pure Zinc 50				
100	—	1-110	10-587	11-647
Commercial Brass:				
Copper 66·5				
Zinc 32·5				
Iron and Lead 1·5				
100	0-579	3-667	3-324	7-570
Muntz Metal (Sheet):				
Copper 70·				
Zinc 29·2				
Iron and Lead 0·8				
100-0	0-438	4-226	2-721	7-385
Muntz Metal (Bars):				
Copper 62				
Zinc 37				
Lead and Iron 1				
100-0	0-501	2-697	3-493	6-691
Prepared Brass:				
Copper 50				
Zinc 48				
Tin 2				
100	0-365	7-04	3-477	10-882

The above table shows how very differently sea water acts upon divers brasses and the influence exercised upon the copper and the zinc composing them, by the existence in them of a very small proportion of another metal; thus, in pure brass the zinc is most rapidly dissolved (which, *en passant*, is the contrary to what takes place in galvanised iron), whilst it acts as a preservative to the copper.

Tin, on the other hand, appears to preserve the zinc, but to assist the action of sea water upon the copper.

The great difference between the action of sea water upon pure copper and upon Muntz metal seems to us to be due not only to the fact that copper is alloyed to zinc, but to the small proportion of lead and iron which that alloy contains; and there can be no doubt that ship-

builders derive great benefit by using it for the keels of their vessels.

We were so surprised at the inaction of sea water upon lead that we were induced to compare its action with that of several distinct varieties of water, viz., Manchester Corporation water—well water—distilled water in contact with air—the same deprived of air—and the following are the amounts of metals dissolved by 200 litres of these waters upon one square metre of surface during eight weeks:—

	Grammes.
Manchester Corporation water.....	2-094
Well water.....	1-477
Distilled water (with air).....	110-008
„ „ (without air)	1-829
Sea water	0-038

These figures require no comment, as they confirm our previous result that sea water has no action on lead, except what arises from friction.

Fine Arts.

THE POURTALES SALE.—This great sale, which commenced on the 6th of February, and occupied twenty-nine actual sale days, closed on the 4th instant. The interest created, and the prices obtained, have been enormous. The collection has remained unsold, in accordance with the will of the deceased Count de Pourtales-Gorgier, for ten years since his death, and there is little doubt that this circumstance has enhanced the receipts by something like 50 per cent. The estimates of the experts, who in Paris fix an upset price at the auction, have been very generally surpassed, and the total amount of the sale falls little short of £150,000. The late Count bought carefully, and at a time when objects of art were low in price in France, and it is believed that the collection has sold for at least five or six times more than its cost. The following are amongst the most interesting of the three thousand and odd items:—*Pictures.*—Albertinelli, Holy Family, sold for a sum equal to £500. Antonello de Messina, pupil of Van Eyck, from whom he learned the art of painting in oil, Portrait of a Man, bearing date 1475, and being the only known work of this artist, purchased for the Louvre at £4,540. Giovanni Bellini, pupil of the preceding, Holy Family, 1824. Angiolo Allori, called Il Bronzino, Portrait of a member of the Medici Family, £2,200. Carlo Dolci, Saint Catherine, £1,080; and Christ in Purgatory, bearing a standard, and giving his hand to Saint Thomas to kiss, picture that decorated the sacristy of a Florentine convent, £728. Francia, Madonna and Child, St. John and an Angel, £860; and a Holy Family, £560. Leonardo da Vinci, Madonna and Child, £3,340. Moroni (who died in 1578), Portrait of a bearded Man, £504. Palme the Elder, Holy Family, £408. Sebastian del Piombo, Portrait (supposed) of a Duc d'Urbain, £8,720. Paul Veronese, Portrait of his Daughter, £820. Philippe de Champaigne, Marriage of the Virgin, formerly the altar-piece of the Chapel of the Palais Royal, in Paris, a long picture, containing about twenty figures, purchased by the Marquis of Hertford for £1,740; Portrait of his Daughter, a Nun of Port Royal, £884. Francis Hals, Portrait of an Officer, also purchased by the same nobleman for £2,040. Rembrandt, Portrait of a Burgomaster, lately in the collection of Mr. Farrer, of London, £1,880; and Portrait of a Warrior, £1,080—two magnificent works purchased for the National Gallery of London. Rubens, beautiful small Portrait of a Noble, bought for the Louvre, £440. Murillo, The Triumph of the Eucharist, a large mystical composition, with many figures, also purchased for the Louvre, £2,700; a Madonna and Child, £720; and Saint Joseph walking with the Infant Jesus, £600. Velasquez, a Young

Warrior, wearing a black cuirass, lying dead in a cavern, known as the "Dead Roland"—a noble work, bought for the National Gallery, at £1,400. Bonington, the Sea Coast at Low Water, £260. Boucher, a Poor Artist Working in his Garret, amid signs of poverty and confusion, £280. David, Portraits of Pius VII. and Cardinal Caprara, £712. Decamps, a Soldier of the Sultan's Guard, a very small but beautiful work, £320. Delaroche, Saint Cecilia, £840; Cardinal Richelieu, in his Barge on the Rhone, leading Cinq-Mars and De Thou to Execution; and its companion picture, Cardinal Mazarin on his Death-bed, the Court playing cards near it, and one of his nieces showing him her hand, sold together for £3,200; and the Temptation of Saint Anthony, £408. Greuze, Innocence, a young girl with a lamb in her arms, £4,008; and Portrait of a Young Girl, a small work, £208. Ingres, Raphael and the Fornarina, £380. Lancret, Women Bathing, £292. Lenain, a French artist, who died in 1648, Six Nobles of the time of Louis XIII. sitting round a table talking and smoking, £700. Claude Lorraine, Italian landscape, Sunrise, from the collection of Mr. William Smith, of London, £1,460. Meissonnier and Francas, figures by the former in a landscape by the latter, £500. Rosa Bonheur, Shepherd guarding sheep and goats, £364. Ary Scheffer, Young Mother, £260. Horace Vernet, Thamar and Inda, £1,408. *Drawings and Sketches.*—A sketch of the Adoration of the Shepherds, by Pinturicchio, called "Il Bernardino di Benedetto," a painter of the Umbrian school, who died in 1513, £200. Pen-and-ink drawing, by Albert Durer, in three parts, bearing date 1510, £180. Crayon drawing, by Prudhon—Helen and Paris reconciled by Venus—£198. *Antiquities.*—The celebrated vase in Oriental red porphyry, from the villa Albani, and known as the Vase of Pallas, £680. Colossal statue in marble of the Emperor Augustus, formerly in the possession of Cardinal Richelieu, purchased for the Berlin Gallery, at the price of £1,048. Statue of Cupid bending his Bow, an antique copy of a work supposed to be by Praxiteles, and of which a similar copy is to be seen in the British Museum, £340. Young Satyr and Panther, Greek, £612. Colossal head, called of Apollo, formerly in the Giustiniani Gallery, and one of the purest specimens of Greek art, purchased for the British Museum at £1,800. The painted Greek vases in this collection were, perhaps, on the whole, unrivalled. One of these, decorated with subjects belonging to the Eleusinian mysteries, fetched £100; and another, with episodes from the story of Theseus and Hippolyta, £404. *Antique Bronzes.*—Small statuette of Jupiter, found at Beaunon, £320. Another of the same personage, seated, found in Hungary, £480. A diminutive figure of Apollo, but very celebrated on account of its antiquity, an inscription upon it carrying it back to the sixth century before the Christian era, £200. Small statuette of Minerva, in the finest style of Greek art, £768. Four pieces of armour, a casque, grieves, arm pieces, and buckler, found at Herculaneum, bought by Prince Napoleon for £520. Small bust of a Roman, unknown, celebrated by Visconti, purchased for the Louvre at £182. Elegant tripod from the ruins of Mataponte, Berlin Gallery, £400. Large ornamental seat in bronze, from Rome, Louvre, £212. Fine bronze vase, from Locris, £280. Another, found in one of the tombs at Vulci, £360. Candelabrum, found with the same, £80. Lampadaire, a bronze pilaster with arms, supporting four small lamps of different forms, from Herculaneum, purchased for the Louvre at £116. *Terra Cotta.*—This portion of the collection contained some very remarkable examples. A small coloured statuette of a woman seated crossed-legged and arranging her hair, found in Athens, fetched the extraordinary sum of £100. Two small fragments of a bas-relief, £86.—A fine Greek cameo, with a single female figure, went for £108; a series of thirty intaglios in rock-crystal, by Valerio Belli, £520; and an ancient glass vase, found near Amiens, £84.—The sculpture in ivory was remarkably choice. A statuette of Hercules, supposed to be the

work of John of Bologna, sold for £656; a small statuette of Venus, by F. Flaman, £286; a tankard, by the same, purchased by M. Thiers for £524; a circular bas-relief, with six figures of children, £284; another, Pan with a group of children, £212; portraits of Jacob Herbroet and Marina Krater, his wife, carved in wood, and bearing the date 1527, attributed to Albert Durer, fetched £240; and a medallion, also in wood, with the head of Ludovico Dangerant, and the date 1529, £36. A bronze bust of Charles IX. of France, life-size, the work of the period, formerly in the collection of the Duc de Berry, sold for £1,800. *Porcelain and Faience.*—This section presented instances as extraordinary as any of the others; a large coupe or tazza of Gubbio ware, sold for £186, and a round dish of the same for a like sum. A large dish of faience d'Urbino, £65; and a vase of the same, £148; a small square of Faenza ware, with a subject after Albert Durer, £126; a large oval dish, by Bernard Palissy, £112; and a grand salt-cellar by the same, £202. But the gem of this portion of the sale was a vase of the so-called Henry II. ware, which was purchased by a private gentleman, M. Van Cuych, for £1,100.—The *Limoges* and other enamels were extremely fine and numerous. A beautiful covered cup, presented to Mary Stuart when she was affianced to Francis II., fetched £1,084; a round basin, *grisaille* enamel, £808; a large dish-tray in exquisite coloured enamels, subject, "The Egyptian Army Drowned in the Red Sea," by Jean Courtois (or Courteis), £1,200; a small ewer to match, £280; and an oval plateau by the same, *grisaille*, £560; a coupe, or large flat glass, of Venetian manufacture, of the fifteenth century, fetched £100; a vase in rock-crystal, a fine work of the sixteenth century, £460; three others, £200, £284, and £352 respectively; a jasper cup, £576; a knife and spoon in silver gilt, supposed to be the work of Benvenuto Cellini, £442; and, more wonderful than all, a pewter ewer and basin, ornamented with arabesques and medallions by François Briot, with his own portrait beneath the basin, was bought for £300. This rapid sketch of a few of the gems will give some idea of what was the Portraits collection, which the hammer of the auctioneer has now scattered over the face of the globe.

PHOTOGRAPHY ON PAINTING CANVAS.—Many attempts have been made to obtain a photographic groundwork for oil paintings, but heretofore without much success; it is said, however, that the Belgians have been more successful than their neighbours. The method adopted is, to use fine canvas, or silk, such as is employed for small and delicate works, simply to cover the surface with a preparation of collodion and chloride of silver, and to expose it and fix it in the ordinary manner just as in the case of paper. It is said that no difficulty whatever arises, provided that the collodion be well selected; if of a nature to dry hard and horny, it will fall from the canvas, and so spoil the work, but if it sets in a smooth, even manner, it can only be removed from the canvas by means of a solvent.

SHAKESPEARE ILLUSTRATED BY DORÉ.—It is said in Paris that M. Gustave Doré, who has already exercised his fertile and picturesque pencil on Dante, Chateaubriand, and Cervantes, is engaged in a series of illustrations of the works of Shakespeare. There is no doubt that M. Doré will find an immense number of passages suitable to his genius, but it is to be hoped, for his own reputation, out of France especially, that he will pay some attention to local characteristics and colouring, and avoid such incongruities as are exhibited in his illustrations of "Athalie," in which we find northern firs and tropical palms most unfortunately mingled—though, it is just possible that, in this case, the author and the illustrator may deserve equal blame; and also, that he will attempt to endow the personages of Shakespeare, and more especially the female characters, with general, nay, universal, physiognomical characteristics, avoiding the conventionality which marks so terribly the otherwise admirable delineations of many of his own countrymen.

Manufactures.

CAST-LEAD TRAPS.—Hitherto stink traps have been made by hand, whether of the S form or otherwise, it not having been found practicable until now to cast them, loam cores being too expensive. They were formed by beating up the lead and joining the parts by solder, a process involving time and labour, and therefore expensive, whilst at the same time the roughness and corners left in the soldering rendered the article more liable to collect dirt and clog. Messrs. Beard and Dent are now employing an invention of Mr. Lowe, an American, who uses cores of gun-metal or cast-steel, composed of several pieces readily put together and easily withdrawn after the casting is made. Under the old system four traps only could be made in a day by a plumber and a labourer, whilst by the new plan, with two sets of corners, four men can make eighteen such traps in one hour. The advantages are:—1. That the traps are considerably cheaper than hand-made traps. 2. That they are of pure and solid lead, without solder or seam of any kind, and as smooth and clear inside and out as pipe made by hydraulic pressure. 3. That they are of perfect regular substance throughout; and, being composed of one metal, are not subject to injurious expansion from hot water, nor are they liable to be affected by the generation of gases, which almost invariably destroy the ordinary trap.

COLOGNE INTERNATIONAL EXHIBITION.—It has been already announced in these columns that the Cologne Exhibition has been deferred to the 2nd June, in order to give foreign exhibitors the benefit of the conditions of the new tariff, but it is not generally known that the scope of the exhibition is limited to certain classes of objects. The whole is to be classed under four heads:—I. Agriculture. II. Domestic Economy. III. Matters relating to Forest Life and the Chase. IV. Horticulture. These denominations must, however, be taken in the widest sense. In the first place, agriculture includes all matters connected with wine, sugar, distillation, &c.; domestic economy—materials and articles of clothing of all kinds, as well as furniture, glass, and other household necessities—while vehicles of all kinds will come under the various classes. The management exhibits a determination to make the undertaking successful. There is no charge for space; the railways of France, Belgium, and the Rhenish provinces have announced a reduction of one-half on the tariff for the conveyance of goods to be exhibited, and the charge for conveyance to or from the terminus to the Exhibition is fixed at 50 centimes per 50 kilogrammes (5d. per cwt.), customs declarations and other formalities included; and no duty will be charged unless the machinery or goods are sold. Moreover, in order to aid the sale of the objects exhibited the commission has devoted the sum of 40,000 francs for the purchase of articles which will afterwards be disposed of by means of a lottery. Medals are to be given in all the classes, and three important prizes, in money, the amount of which, however, is not yet made known, for the best steam plough, the best fire pump, and the best locomotive for common roads, respectively.

NEW KIND OF MIRROR.—The Paris correspondent of the *Chemical News* writes that M. Dode, a provincial chemist, has introduced platinum mirrors, which are greatly admired, and which present this advantage, that the reflecting metal is deposited on the outer surface of the glass, and thus any defect in the latter is concealed. The process, which is patented here, is described as follows:—Chloride of platinum is first made by dissolving the metal in aqua regia, and driving off the excess of acid. The neutral chloride is then dissolved in water, and a certain quantity of oil of lavender is added to the solution. The platinum immediately leaves the aqueous solution and passes to the oil, which holds it in suspension in a finely-divided state. To the oil so charged the inventor

adds litharge and borate of lead, and he paints a thin coat of this mixture over the surface of the glass, which is then carried to a proper furnace. At a red heat the litharge and borate of lead are fused and cause the adhesion of the platinum to the softened glass. The process is very expeditious. A single baking, M. Dode states, will furnish 200 metres of glass ready for commerce. It would take fifteen days, he says, to coat the same extent with mercury by the ordinary plan. A considerable reduction in the cost of looking-glass is expected from the adoption of this process; for any glass, even the common bottle metal, will serve to be coated.

ANILINE BLACK DYE.—French manufacturing chemists and dyers have of late given great attention to the production of a black dye from the aniline source, and M. Charles Lauth has invented a new process, and his black aniline dye has been used at Mulhouse for printing from 15,000 to 20,000 pieces of maulin. The system employed by M. Lauth is to print with matter insoluble in water and acids, but which becomes soluble afterwards on the fabric. In his own words the process is thus described:—"My receipt for black aniline dye consists in printing with chlorate of potash and aniline salt on a preparation of soluble iron or copper, but I give the preference to sulphite of copper. The printed stuff is then exposed to oxidation and afterwards washed, when the black is perfectly fixed." The acid of the aniline salt decomposes the chlorate of potash; the chlorine, or its oxides, transforms the copper into sulphate of copper; and the last-named product aids in the oxidizing process. The advantages claimed for M. Lauth's process are as follows:—The sulphite of copper, being entirely insoluble, has no effect on the roller and scrapers; the colour in its soluble state containing nothing but chlorate of potash and an aniline salt, will remain unchanged for a long period; it is cheap, costing only about 90 centimes a litre (4s. 9d. per gallon English); it fixes easily in a temperature of 20° centigrade (less than 69° Fahrenheit); it may be applied to almost all kinds of work, and, when proper precautions are taken, has no injurious effect whatever on the tissue. The aniline black of M. Lauth is declared to resist not only ordinary but chemical agents, and so to incorporate itself with the fibres of the printed fabric that nothing can afterwards move it.

Commerce.

TEA IN HILL TIPPERAH.—The tea tree has been found in Hill Tipperah by Mr. Civil Assistant W. C. Rosenrode, whilst carrying on the approximate triangulation in advance last season, at a hill called Sabrong, in lat. 23 deg. 2 min. and lon. 91 deg. 48 min. There is another tree in this country, called, in Bengal, the "maritcha," growing up to twenty-five or thirty feet in height, the venation of the leaves of which is the same as that of the tea. The tea tree will grow and thrive wherever the maritcha is found. The clove plant has always been found indigenous on the table-land between Gojalia and Tulamara. Dr. Cleghorn pronounces it a *cinnamomum*. Now that tea is known to thrive in Chittagong and Tipperah, the *Friend of India* sees no reason why, in time, the whole of the low hill ranges which lie between Assam, Burmah, and south-western China, should not be cultivated.

OIL FROM TEA SEED.—It has lately (says the *Englishman*) been an important question among tea-planters, what to do with the large quantity of tea seed now available. It will, therefore, be an interesting fact for them to learn that a trial was recently made at Calcutta to produce oil from tea-seed. The result would seem to prove that three maunds of tea-seed will yield about one maund of oil. The oil is very similar in appearance to olive-oil. The *modus operandi* is very simple. The seed is first crushed in a crushing machine, and then pressed in another worked horizontally by an Archimedean screw.

TEA IN INDIA.—The *Calcutta Englishman* says:—Perhaps the most interesting feature of the current history of Bengal is the progress in outlying and hitherto uncultivated tracts of country. Foremost among such tracts are Sylhet, Cachar, and Assam. In Sylhet the progress last year has been great beyond all precedent. The first tea garden was laid out in 1857, but English enterprise did not take root in the province till 1860, when the first of the existing plantations was started. In 1862 more than 1,000 acres were already under cultivation, and in 1863 the number had increased, in round numbers, to 2,500. In 1863 the yield was 31,200 lbs. of tea and 526 maunds of seeds, and last year these numbers have suddenly risen to 81,200 lbs. of tea and nearly 1,500 maunds of seed. This increase is made in spite of the greatest scarcity of labour, nearly one-third of the coolies being imported. In this province at least the government seems satisfied that the coolies have no serious grievance to complain of. The labourers are allowed extra remuneration for doing more than their allotted task, and their average earnings, according to the report, amount to five rupees a month each cooly. The wages of such men in a Bengal district do not exceed seven pice a day, or something less than three rupees, counting six days to the week. Applications for 75,000 acres await disposal by the collector. In Cachar the cultivation is on a larger scale. Some of the plantations have been in operation for seven years, and cultivation is in progress in 110 estates, aggregating more than 250,000 acres. At the end of 1863 the capital expended was close on 40 lacs, producing a return of 418,248 lbs. of tea and 1,019 maunds of seed; but during the past year the yield has more than doubled, and the estimated turn-out is 823,380 lbs. of tea with 2,573 maunds of seed. The difficulty in procuring labour is even greater in Cachar than in Sylhet. In the latter nearly one-third is imported, in the former the proportion is fully three-quarters. In Assam nearly 200,000 acres have been taken up, affording employment to 28,000 labourers, and sending about £300,000 worth of tea to England, besides what is consumed in India. From Darjeeling no precise information appears to have been obtained for the year 1864, but the purchasing of estates is going on rapidly. The out-turn during 1863 was close on £100,000. The Ramgurbh Tea Company have more than doubled their land under cultivation last year in Chota Nagpore; another company is busy in a range of hills to the south-east of Hazareebaugh, and tea-planting in central India is now a *fait accompli*. The young plantations are said to be vigorous and healthy, and the very large proportion of seed that has germinated proves, more conclusively than any geological report, that the soil is well adapted for tea. Labour is cheap, abundant, and to be found on the spot. Taking this into consideration, Col. Dalton observes that, even if the leaf-producing powers of the plant were only half as great in Central India as in Assam and Cachar, the profits of plantations would be equally good. In Chittagong, too, the soil is reported well adapted for tea and coffee cultivation. During the past financial year several tea planters visited the district and applied for grants. Some difficulty is anticipated in making new allotments, "owing to the rather loose and hap-hazard way in which large tracts of land were, so to speak, given away rent-free for long periods at the settlement of the district." It will be remembered that a sample of Chittagong tea won a medal in the Agricultural Exhibition at Alipore. A small estate has been in cultivation for many years near the Sudder station, and a considerable number of acres has recently been broken up for the plant in the hill tracts. We have not space to-day to enter more fully into the report. The figures given in it are under the truth rather than over it, and they refer only to a single branch of English enterprise in India. We find that in one province this portion of British enterprise has trebled itself during the past official year, and in another has doubled itself. The returns of only two tea-growing districts are given in full, but we believe that

the same proportion holds good in all. This single branch, tea-planting, has changed the destiny of whole provinces greater in area than England, and turned vast tracts of unhealthy, unprofitable wastes into revenue-paying and life-supporting land. It has belted our North-Eastern frontier with a ring of gardens, and placed an advance guard of Englishmen between the plains and the hill tribes. But this is not all. It has furnished an accessible and profitable vent for the over-crowded population in Bengal proper, and done much to ameliorate the condition of the labouring classes throughout the whole country.

Colonies.

MANUFACTURES OF NEW SOUTH WALES.—There are 180 mills for grinding and dressing-grain. Of these, 129 are steam mills, 20 are driven by water, 13 are windmills, and 18 are worked by horse-power. Thirty-three of these mills are in the pastoral districts. In the year 1860 the number of mills was 193, since which date the number has continuously declined. The number of establishments or machines which are classed under the head of manufactories or works in the old settled districts is 1,568, of which only 323 are in Sydney, and in the pastoral districts 1,768. But under this heading is included the following miscellaneous assortment. Connected with agriculture:—Tobacco factories, steam bakeries, reaping and threshing machines, chaff-cutters, bone crushers. Connected with the pastoral interest:—Soap and candle works, cloth factories, tanneries, fellmongering, meat preserving, boiling down, wool washing, steam wool pressing. Connected with articles of food and drink:—Distilleries and sugar refineries, rectifying and compounding establishments, breweries, steam coffee mills. Connected with building:—Potteries, brick-making, lime-kilns, and saw-mills. Connected with metals:—Millwrights, iron and brass foundries, type foundries, engineering works. Miscellaneous:—Quartz-crushing machines, stone crushing machines, hat manufactories, rope walks, salt works, dye works, gas works, anchor works, steam alips, patent alips, dry docks, fire engines, steam engines, railways, bark cutters, ice manufactories, steam printing presses, water works, gold-washing machines and ship-building yards. This colony appears to be behind some of the neighbouring colonies in respect of improved agricultural implements, three or four of them having imported steam ploughs. The woollen manufacture in 1863 was only to the extent of 64,650 yards, which was only half that of the preceding year. The manufacture of soap was also below that of the preceding year, though the number of establishments had slightly increased. The manufacture of candles was to the extent of 17,237 cwt. There are thirty-nine boiling-down establishments in the colony, of which ten are in the pastoral districts. At these places there were slaughtered 7,514 sheep and 30,335 head of horned cattle, from which was produced 67,694 cwt. tallow. This was an increased production over the previous year. During each of these two years about a quarter of a million sheep were slaughtered. "But," says a Sydney paper, "sheep are too valuable now to be boiled down. The necessity for stocking all new runs has created a great demand, and everything that can crawl on four legs has a value. But if the multiplication of stock continue at its present rate, and especially if the price of wool should decline, the sheep will find their way again in larger numbers to the boiling pot."

NEW ZEALAND INDUSTRIAL EXHIBITION.—This exhibition was opened at Dunedin on the 12th January. The Governor was not present, and his honour the Superintendent filled his place. The exhibition is stated, considering all circumstances, to be a marvel of success. The natural products and manufactures of the colony are well represented, and the collection affords striking

proofs of the great resources of New Zealand. Owing to the unfortunate detention of the *Ramsay*, in which ship are the Indian and British exhibits, the exhibition is deprived of one of its chief attractions. The obelisk representing the bulk of gold got in Otago is the most prominent object; and opposite it stands the elaborate and beautiful apparatus for the lantern of the Cape Saunders lighthouse. The displays of gold and jewellery, in several cases, attracted much admiration. At the northern end of the hall, in the dividing line between Otago and England, stands the dais which was intended for the governor. At the other end of the hall stands the Wellington-built organ, contributed by Mr. Lewis; and in front of the organ was an orchestra for fifty members of the Philharmonic Society. A line of flags, festooned near the ceiling, extended the length of the building. Above the entrance there was hung a very large piece of carpet-work, the centre of which represents Napoleon III. presenting to Queen Victoria a document bearing the words, "The Treaty of Commerce—a further proof of our friendship." At several points, rich carpeting and other specimens of manufacture were displayed in front of the gallery; and a broad band of crimson cloth stretched round the building, just below the line of the glass forming part of the central roof. The interior of the building is said to have a light appearance, despite the absence of chromatic colouring on the walls and ceiling. In the address of the Royal Commissioners to the Superintendent, they describe the objects of the exhibition as being, "to collect together some of the evidences of the remarkable progress of the colony, which attest the energy of its inhabitants; to place them side by side with the products of other colonies and the parent country; to afford the opportunity of comparing the raw material of the newly occupied country with the finished manufactures of the old; to gratify successful enterprise by an acknowledgment of its merits; and to encourage further exertion by the approval of what has been already done." They go on to say, "that but for the unhappy differences which have for so long time past severed the two great sections of the American Union, very considerable additions from those States would have been made to the collection. The Province of Otago recognises with sentiments of the deepest gratitude the zeal and liberality which have marked the co-operation of other provinces and contributors, but we desire to mention the fact that the building in which the exhibition is contained, has been erected at the sole cost of this province." They draw particular attention "to the collections illustrative of the geology of the colony, both on account of their extent and of the intrinsic value of such collections in their bearing on the development of the resources of a country from the mineral wealth of which so much has already been derived, and so much may be confidently expected." They also contrast with these more material evidences of their resources, the proof of social and intellectual refinement which is to be found in the exhibition of fine arts, one which they believe will be admitted to be extremely creditable to the taste and practical skill in art of so young a colony. His honour the Superintendent, in his reply, addressing the Commissioners, said:—"You have been engaged in a noble as well as an arduous work, and you will receive the reward of your self-sacrificing labours in the knowledge that through their means New Zealand has become entitled to claim a higher place than has yet been allotted to it amongst the colonies of Great Britain. The beneficial effects of this exhibition on the colony may not be immediately appreciable, but you have sown good seed in a fertile soil, and may confidently look for an abundant harvest. Through this exhibition New Zealand will be brought out from its obscurity into a face-to-face meeting with the outer world. Many of its great and varied resources will be exemplified—its vitality and progressive character will be attested, new industries will be created, existing ones revived, public taste and morals will be elevated, and a generous emulation between various provinces and colonies will be promoted."

Obituary.

AUGUSTE HYACINTHE DEBAY.—France has lost a very able artist by the death of this gentleman, which happened a few days since. M. Debay was both painter and sculptor; three of his pictures are at Versailles, "The Enrolment of the Volunteers in 1792," "The Meeting of Henry the Eighth and Francis the First on the Field of the Cloth of Gold," and "The Battle of Dreux." There is one in the Luxembourg gallery, subject from the story of Lucretia. He also executed, amongst other works, the monument to the memory of the late Archbishop Affre, and a statue of Perrault for the new Louvre. His most celebrated work, however, and certainly that by which he will be most generally remembered in England, is "The First Cradle, Eve with Cain and Abel in her lap," a beautiful marble group, which attracted great attention at the Great Exhibition of 1851. M. Debay obtained the very rare honour of first-class medals, both for painting and sculpture, at the Paris Fine Art Exhibitions, the former in 1831 and the latter in 1855. He was only in his sixty-first year when he died.

Publications Issued.

TRAITÉ DES BREVETS D'INVENTION. By Augustin Charles Renouard. 8vo. (*Guillaumin and Cie., Paris.*)—At present, when the law of patents is under consideration, it is necessary to know what are the opinions of enlightened foreigners with respect to this much vexed question, and what results of the patent system have been noted in other countries besides our own. M. Renouard is a Counsellor of the Court of Cassation in Paris, and a member of the French Institute, and in every way he has a strong claim on the attention of both the friends and opponents of the patent system. The work, of which the title is quoted above, is the third edition, augmented and materially altered, of a treatise first published so long ago as 1825, and which has always enjoyed a high reputation. M. Renouard has also published other important works on the rights of authors and artists, and on the principles of civil, commercial, and international rights. The work in question is divided into three parts; the first treating of the theory of legislation with respect to inventions, and of its history in France and in each of the other principal states in the civilised world; the second, detailing and explaining the practice of the law in France; and the third being a collection of the Acts passed in France on the subject, from 1844 to the present time. M. Renouard is a warm supporter of the right of the inventor to protection. He says:—"Respect for the rights acquired by labour is one of the fundamental principles of social order. It would be a fatal error to isolate this from that which is due to property." As regards the mode of exercising that right, and conciliating it with those of the public, M. Renouard says:—"The duty towards society is to prevent the public from losing the invention, which, by the very act of publication, enters into the domain of the public mind." . . . "The legislation problem consists in finding the proper mode of payment." He discusses the proposed system of public recompense, and that of fixed fees for licences, but rejects them both in favour of the principles which form the foundation of the patent laws of all countries; and he declares it to be his profound conviction that the objections raised against the present law are, when examined in a philosophic spirit, of very little weight when placed in the scale against the rights of the inventor. Those who differ from M. Renouard as respects his conclusions, will find a vast amount of historical matter of great interest in his work, especially in the chapters referring to the ancient Industrial Corporations in France, and to the regulations and privileges appertaining to manufactures and to the condition of the inventor previous to 1791.

MANUAL OF THE TURKISH BATH: HEAT A MODE OF CURE AND A SOURCE OF STRENGTH FOR MEN AND ANIMALS.—Edited by Sir John Fife M.D., senior surgeon to the Newcastle Infirmary. (*John Churchill and Sons.*)—This work contains views and opinions taken from the writings and sayings of both medical and non-medical men in reference to the efficacy of the bath. The editor, in his preface, says, "in the year 1859, having previously satisfied my own mind of the efficacy of this process, I brought it under the consideration of the Pathological Society of Newcastle, and afterwards addressed on the subject the House Committee of the Newcastle Infirmary, who, encouraged by his Grace the Duke of Northumberland, well experienced during his eastern travels in the value of the Turkish bath, entered energetically into the enterprise of constructing such baths for the hospital. The effect of this wise measure has been essentially economical, inasmuch as by shortening considerably the necessary period of confinement within the walls of the hospital, less expense has been incurred in restoring many hundreds of working men to their habits of useful industry. Great must be the value of a process which, in a few minutes, will secure a general diaphoresis, bring the circulation to the extremities, and equalize the arterial action instead of permitting a disordered influence to direct an undue flow upon one tortured part to the comparative deprivation of arterial blood to other and distant structures; a process competent to allay spasm immediately in many cases which might resist all other diaphoretics, or exhibit their effects only in gastric and intestinal irritation." The work is divided into two parts; Part I. treats of the action of the bath on man, and commences with a dialogue, in which Messrs. Erasmus Wilson, Witt, and Urquhart took part, and in which the question of "Heat, how useful to man and how used by him," was discussed; written from short-hand notes. This is followed by a second dialogue, being a conversation between Mr. Urquhart and the members of the London Medical Society at Rickmansworth. Next comes a paper read by Mr. Urquhart before the Society of Arts, "On the Art of Constructing the Turkish Bath;" then a lecture by Mr. Urquhart, "Why Does Man Perspire?" and articles under the following heads:—"Consumption Produced by Habits, not Climate;" "Treatment of Consumption by the Turkish Bath," by Dr. Leared, &c.; with papers referring to the treatment of cancer, leprosy, hydrophobia, and apoplexy; cure of cataract; the construction of a bath with radiating heat for invalids, comprised in a correspondence with Sir John Fife, "The introduction of the bath into lunatic asylums and naval and military hospitals, with Dr. Robertson's experience at the Sussex Lunatic Asylum," and a paper on "Heat rays, sun rays, electricity and vital power," concludes Part I. To all these papers a large amount of notes is added. Part II. relates to the action of the bath as regards animals, and consists of two papers, one entitled "The Bath in the Farm," which refers to the training of horses, the treatment of domestic animals, and Admiral de Rons's views "On the Bath for Horses;" and the other called "Four Years' Experience of the Bath on an Irish Farm," by J. E. Scriven, Esq. An appendix concludes the work. There is a vast deal of useful information connected with the bath to be found in this small volume, and much that is worthy of impartial consideration. In statements by non-professional persons, it is necessary, says the editor "to guard against hasty conclusions on the one hand; or, on the other hand, the rejection of statements that may seem at variance with the therapeutic science of men experienced in the value and justly confident in the indications which therapeutics afford."

L'ANCIENNE ACADEMIE DES SCIENCES. By Monsieur L. F. Alfred Maury. 8vo. (*Didier and Co., Paris.*) This is a companion volume to one by the same author, M. Maury, of the French Institute, Professor of History and Morals at the College of France, on the Academy of Inscriptions and Belles-Lettres. Like the latter, this

gives a detailed history of the rise and progress of the academy of which it treats, but, in a practical point of view, it is of far greater importance, for it presents also a history of the march of science itself, while the Academy of Belles-Lettres could not furnish any array of positive facts for such a history of subjects. M. Maury says, and with justice, that didactic treatises seldom afford sufficient information upon the various steps which have been taken in science, and of the successes and failures which have alternated with each other; and thus the man of science, and more especially the student, is not furnished with those data which might prevent his falling into the very errors which his predecessors have discovered and often surmounted. Again, M. Maury is a devoted admirer of science, and places it far before literature, or rather before works of imagination, for he says:—"Science requires a logical capacity, a power of concentration and perseverance, a genius for abstraction and generalization, which the purely literary man does not want." M. Maury carries his work down to the end of the last century only, for, he says, in the first place, the scientific epoch which then opened is not yet closed; and, secondly, that the science of the nineteenth century has assumed such vast dimensions, and ramified in such an extraordinary manner, that no one man is capable of grasping the threads of such a complicated skein. The progress of science in all its branches, and in other countries as well as in France, is traced with learned care and explained in a lucid and highly-interesting manner. Amongst the subjects which are treated with the greatest fullness are astronomy, the applications of mathematics to physical science, natural history, and chemistry, but nothing is omitted which can explain the growth of each branch of the scientific tree, and the connection which exists between them. M. Maury exhibits complete impartiality in estimating the labours of the philosophers of other nations, and Englishmen will have no cause to complain of his appreciation of their countrymen's achievements.

METEOROLOGICAL DIAGRAM, showing the daily elements throughout the year 1864. By C. O. F. Cator, M.A. (*E. Stansford, Charing-cross.*) This diagram exhibits, by means of curves, the daily barometric pressure, temperature, direction of the wind, rainfall, and weekly number of deaths in London. The Greenwich mean temperature for each day as well as that of London is given.

Notes.

THE PAINTER'S COMPANY'S EXHIBITION OF GRADING, DECORATION, &c.—The Company have issued a notice that as this Exhibition, after five years' existence, has not increased either in the quality or the number of the specimens presented for competition, it is concluded that an annual demand on the trade for specimens is too frequent, and, therefore, the Company have resolved in future to hold the exhibition once in two or three years, according as the wishes of the trade may be expressed. In order to ascertain the general feeling of those interested, and, if possible, to excite a more energetic response on the part both of masters and journeymen than has hitherto been manifested, the Master, Wardens, and Court solicit communications on the subject, which will receive the utmost attention, and which will regulate the future proceedings in relation to the exhibition. Under these circumstances, there will not be an exhibition this year (1865) at the Hall; but one will be held next year if there is an adequate response from the trade, both masters and journeymen.

WATER SUPPLY OF PARIS.—The great works for supplying the houses and city of Paris with water are being pushed forward with remarkable activity. In the *Journal* of the Society, of March 10th, some account was given of the extensive reservoirs at Ménilmontant and Belleville, and of the aqueduct for bringing the waters of the

Dhuis to the metropolis; a few more particulars may now be added. The other day, the loungers in the neighbourhood of the tower of Saint Jacques de la Boucherie, were astonished at the appearance of a number of cast iron pipes, measuring more than fifty-four inches in diameter; these tubes weigh about a ton each, and are to be laid in the tunnels of the new sewers, and will form a portion of the Dhuis aqueduct. A steam-engine of fifteen horse power will raise the water from the reservoir of Ménilmontant to that of Belleville, and the latter, from its elevated position, will supply the highest portions of the city, which at present depend entirely on manual labour for their water. The new sources now being brought into use are calculated to bring to Paris 300,000 cubic metres of water in twenty-four hours; one fifth of this quantity is to come through the Dhuis aqueduct. In order to bring the waters of the Marne to Ménilmontant, the authorities of the city of Paris have purchased the waters and usine of St. Maur, which were the property of Messieurs Darblay and Béranger, the great millers; turbines of about 400 horse-power are now being up set at St. Maur for this service, and two conduits of cast iron are now being laid down, to connect the turbines with the reservoir of Ménilmontant; each of these conduits is nearly nine thousand yards in length.

CITY HORTICULTURE.—According to the *Building News* Mr. Morris, the architect, has proposed to the authorities to try terrace gardening in Trafalgar-square. He advocates the formation of a new terrace to the south of the Nelson column, the central space being diversified by the introduction of suitable plants, shrubs, and low-growing trees. Portable trees, such as adorn the walks of the Tuileries, would be placed on the Pall-mall terrace, as well as within the enclosed areas of the National Gallery. The effect, observes our contemporary, would be unlike anything which London now offers, and the works of architecture and sculpture would be relieved and harmonized by the presence of horticulture.—The first of a series of city flower shows was recently held, at Albion Hall, which is situated within a stone's throw of the Bank of England by way of Moorgate-street.—The following hints on window gardening for the working classes are by Mr. Walter H. Bosanquet:—*The Flower Pot.*—Do not paint the outside of the flower pot, but keep it as clean as possible. Before making use of a flower pot, if it be new, dip it into clean water; if it be an old one wash it perfectly clean inside and outside. Before filling it with mould, cover the hole at the bottom with a piece of broken pot, and over that, place two or three layers of small stones. Put the coarse mould at the bottom and the fine mould at the top. *The Seed.*—Do not sow the seeds too deep. Sow large seeds, such as sweet peas and nasturtiums, one inch deep, but let small seeds, such as mignonette, be only slightly covered. Until the seeds come up, water them as gently as possible, or cover the mould with wet moss. *Annals.*—These are raised from seed and only live one year. The sorts called "hardy" and "half hardy" may be raised as window plants. Sow the seeds at the end of March or the beginning of April, and keep those sorts which are called "half-hardy" in-doors until the warm weather comes. Thin the young plants by degrees, but do not leave too many, or they will not have room to grow. *Watering.*—Do not give any water until the mould feels dry, but then water thoroughly, and throw away the water which runs through into the saucer, unless the weather is very warm and dry. Water gently, so as not to wash a hole in the mould or uncover the roots. Use rain water as often as possible, or water which has been long exposed to the air. In winter only give sufficient water and warmth to keep the plant alive. *Light.*—Keep the plants close to the window and turn them as often as the leaves get drawn in one direction. Shade the flower pot from the hot sun, but not the plant, unless the heat is very great. After dark keep the plants, if possible, in a dark, cool room. *Air.*—Give the plants as much fresh air as possible through

the window if the air is not very cold. Do not leave door and window open at the same time. Plants which have been exposed to the fresh air become much more hardy than those which are confined in warm, close rooms. *Cleanliness.*—This is equally important for the well-being of plants and men. Whenever the leaves and stalks get dusty or dirty, wash them with a sponge and lukewarm water. Remove your plants from your rooms while you are dusting or cleaning them. Expose your plants as often as possible to warm soft showers, in order to wash and refresh them. *General Directions.*—At night place the plants on or near the ground, or leave the window slightly open. When the surface of the mould becomes hard stir it up carefully so as not to disturb the roots. Pick off all dead leaves and stalks. Do not buy greenhouse plants, but hardy plants, which are suitable for planting out of doors.

NEW THERMO-ELECTRIC PILE.—M. Edmond Becquerel, of Paris, has arranged a new thermo-electric pile, which is said to exhibit great activity. In place of bismuth and copper, he makes use of sulphite of copper, cast at a heat a little above its point of fusion, and metallic copper. One of these discs of sulphite of copper, placed between two of copper, forms an element; and ten of these elements combined, having one extremity plunged in a sand bath maintained at the temperature of 212° Fahrenheit, and the other in cold water, form a pile which is said to be powerful enough to work a telegraphic apparatus.

MEETINGS FOR THE ENSUING WEEK.

- MON.**...Antiquaries, 2. Annual Meeting.
Philosophical Club, 6. Annual Meeting.
R. Geographical, 8½. 1. Mr. Lawrence Oliphant, "On the Bayano River, in the Isthmus of Panama." 2. Mr. R. Cross, "A Journey from the foot of Chimborazo to Bogota, across the Central Andes."
British Architects, 8.
Actuaries, 7. 1. Mr. G. W. Berridge, "On the Graduation of a Table of Mortality." 2. Mr. M. N. Adler, "On Government Insurance Rates and Regulations."
Royal United Service Inst., 8½. Staff-Commander Fred. J. O. Evans, R.N., F.R.S., "The Magnetism of Iron and Iron-clad Ships."
TUES....Society of Arts, 8. Cantor Lectures. Dr. F. Crace Calvert, "On some of the Most Important Chemical Discoveries made within the last two years." (Lecture III.)
Medical and Chirurgical, 8½.
Civil Engineers, 8. 1. Discussion on Capt. Tyler's paper "On the Festinog Railway." 2. Mr. Calcott Reilly, "On Uniform Stress in Girder Work."
Zoological, 8½.
Ethnological, 8. Rev. James Brodie, "Observations on the Peculiarities of National Pronunciation, as a means of Tracing the Origin and History of Nations."

Patents.

From Commissioners of Patents Journal, April 14th.

GRANTS OF PROVISIONAL PROTECTION.

- Air, engines worked by heated—905—J. Planchbeck.
- Bags, securing the frame of travelling—816—L. A. Leins.
- Barrels, preventing the leakage of—815—A. V. Newton.
- Bleaching, treating the waste liquids obtained in—797—H. Potter.
- Beds, apparatus for lowering ships—890—A. Chaplin.
- Bollers, steam—865—E. B. Wilson and J. Howden.
- Bottles, stoppers for—814—C. H. Crowe.
- Boots and shoes—784—D. Gourley.
- Bread, apparatus for cutting—792—W. Berry.
- Bricks, manufacture of—839—A. and A. Lockwood, jun.
- Bridges, construction of—888—F. A. Leigh.
- Cattle, apparatus for preparing food for—827—R. Willacy.
- Chimneys, preventing smoky—811—B. Greenwood.
- Cigars, mouth piece for—776—T. Oliver and J. W. Munro.
- Cloth, apparatus for manufacture of—821—J. Lees and M. Mellor.
- Cotton, mules for spinning—819—W. Mayall, J. Knott, and W. Dennis.
- Blitz, refriguge and digestive—874—A. D. Gascon.
- Fabrics, apparatus for printing—870—J. Miller and J. Laing.
- Fabrics, weaving ornamental—810—J. Macaulay and R. Watson.
- Felloes, machine for dressing—794—H. S. Jacobs.
- Fire-arms—790—R. J. Gatlin.
- Fire-arms—890—A. F. Tronchon.
- Floor cloth, machinery for manufacture of—768—J. H. Kidd and J. C. Mather.
- Forging machines—882—J. Wright.
- Gas burners—876—F. A. Mocuquard.
- Gas meters—917—J. Bathgate.
- Glass, ornamental articles made of—848—J. Williams.
- Gun locks—838—D. Arnold.
- Hammers, atmospheric—863—J. Vaughan.
- Hats, felt—941—C. Vero.
- Horses, apparatus for grooming—869—J. Norris, jun.
- Ink, manufacture of—836—W. E. Newton.
- Iron, manufacture of sheet—409—W. E. Newton.
- Iron, treatment of certain products obtained in the smelting of—850—T. Horton and D. S. Price.
- Iron, manufacture of balls of—957—J. Player.
- Iron, reducing and melting—899—W. Brookes.
- Lace, manufacture of—971—F. E. Enson.
- Links, fastenings for sleeve links—847—H. Jenkins.
- Liquids, apparatus for refrigerating—891—J. Henderson.
- Looms, motion for—769—E. Pilling and J. Harper.
- Machines, apparatus for feeding printing—812—E. Field and F. Wise.
- Machines, sewing—826—A. Balliol.
- Machinery, cork cutting—636—W. Clark.
- Matters, treating fatty—892—B. Childs, jun.
- Nails, machinery for cutting—896—R. C. Robinson.
- Oil, apparatus for distilling—727—W. E. Newton.

- Ores, apparatus for washing—963—H. Simon.
- Paper, utilization of materials for manufacture of—703—J. Webb.
- Petroleum, casks for storing—834—J. B. Brown.
- Photographs apparatus for mounting—915—J. H. Smith.
- Photographic productions, ascertaining the presence of fixing agent in—877—T. Reising.
- Pictures, photographic—818—E. Pettit.
- Pianofortes—965—B. Johnson.
- Points and switches, railway—844—H. C. Hurry.
- Power, obtaining motive—840—V. Baker.
- Pump, apparatus for hand or steam—18—G. Hodgson and J. P. Pump—814—W. Clark.
- Pumps—943—C. D. Young.
- Pumps, force—951—R. Baynes.
- Railways, construction of rails for—832—W. Loeder.
- Railways, street—923—E. A. Brooman.
- Railway trains, communication between passengers and guard of—81—A. I. L. Gordon.
- Railway hoists, propelling waggons in connection with—85—G. Greenish.
- Railway trains, passage of the guard from one end to the other—864—J. O. Thompson and J. J. M. Green.
- Redactors, apparatus for holding lamp—704—W. Clark.
- Rice, treatment of—842—J. H. Johnson.
- Sails, fastenings employed in metallic—963—W. Miller and D. L. Ratcliff.
- Sawing wax, apparatus for melting—821—W. Banger.
- Spinning, mules for—850—J. Todd.
- Spittoons—852—J. H. Johnson.
- Steam, motive power by the aid of—949—W. Brookes.
- Steel, hardening and tempering—880—E. Savage.
- Steel, rolling or forging—926—W. Gray.
- Smoke, furnaces for consumption of—862—C. Matthews and J. Fawc.
- Silk, apparatus for winding—921—W. Kilbey.
- Stoves, &c.—826—J. C. Morgan.
- Substances, expressing liquids from pulpy—856—W. E. Hewitt.
- Valves—754—W. Roberts.
- Ventilators, hat—961—R. Stanle.
- Weaving, looms for—824—G. H. and J. A. Castree.
- Weaving, looms for—907—L. Bridge.
- Wool separating—811—S. Saville.
- Worsted carding—820—H. Oakes.
- Yards, machinery for winding—901—A. Turner.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MAY 3.—"On Colonization; its Aspects and Results." By WILLIAM STONES, Esq.

MAY 10.—"On the Art of Laying Submarine Cables from Ships." By Captain JASPER SELWYN, R.N.

CANTOR LECTURES.

The Third Course for the present Session, consisting of six Lectures, "On Some of the Most important Chemical Discoveries made within the last Two Years," by Dr. F. GRACE CALVERT, F.R.S., F.C.S. (Corresponding Member of the Royal Academy of Turin; of the Société Industrielle de Mulhouse; of the Société Impériale de Pharmacie de Paris, &c.), is now being delivered on Tuesday evenings, at Eight o'clock, as follows:—

MAY 2ND.—LECTURE 4.—On the Discoveries in Physiological Chemistry.

MAY 9TH.—LECTURE 5.—On the Discoveries in the Chemistry of Rocks and Minerals.

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

Proceedings of the Society.

TWENTIETH ORDINARY MEETING.

Wednesday, April 26, 1865; Peter Graham, Esq., Member of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Bean, Alfred W., Danson-park, Welling, Kent, S.E.
Dent, William, 21, Newcastle-street, Strand, W.C.

Gover, William, Italian-villa, Lee-road, Blackheath, S.E.
Hancock, C., 6, St. Germain's-villas, Lewisham, S.E.

The following candidates were balloted for and duly elected members of the Society:—

Bourne, Geo. S., R.N., Royal Hospital, Greenwich, S.E.
Brackenbury, Capt. C. B., R.A., 1 Adelaide-place, Woolwich-common, S.E.

Brady, Francis, 12, Limes-villas, Lewisham, S.E.

Brumley, Charles, 6, St. John's-road, Brixton, S.

Burt, C. J. T., Roadside, West Hill, Putney, S.W.

Clark, Edward, 2, Rose-villas, Montpelier-road, Peckham-rye, S.E.

Cotterill, W., Norbiton-park, Kingston-on-Thames, S.W.

Danby, Thomas, 7, Parliament-street, S.W., and 31, South-grove, Peckham, S.E.

Dolan, H., Park-hill, Clapham, S.

Eden, Frederick Morton, Capel-house, Kew, W.

Farnall, Harry Barrard, Poor Law Board, Whitehall, S.W.

Field, Hamilton, Clapham-park, S.

Folkard, Augustus, Haslam-house, Lewisham, S.E.

Gibson, John, 1, Era-place, Surrey-lane, Battersea, S.W.

Goodwin, Rev. Thomas, M.A., Croom's-hill, Greenwich, S.E.

Gowan, George D'Olier, Wood-lawn, Dulwich, S.E.

Graham, John, 74, Manor-street, Clapham, S.

Harker, George, Uplands, Sydenham, S.E.

Harrison, C. Wrightman, Pneumatic Loom Company, 26, Lombard-street, E.C.

Hawley, Henry J., 4, Foxgrove-road, Beckenham, S.E.

Herapath, John, Catford-bridge, Lewisham, S.E.

Hills, F. C., Denmark-hill, S.

Hoblyn, Thos. Hallam, Rickling, Bishop's Stortford.

Holloway, William, 4, Park-road-villas, Battersea, S.W.

Hosegood, Thomas W., Rosendale-villa, West Dulwich, S.

Jerram, E. J., 3, Cedars-road, Clapham-common, S.

Johnson, John G., Assay-office, 18a, Basinghall-st., E.C.

Legg, George, 61, King William-street, E.C.

Lewis, Thos., Somerset-lodge, 36, London-rd., Croydon, S.

Lord, W. B., R.A., 37, Stockwell-park-road, Brixton, S.

Macandrews, J., Roehampton-lodge, Roehampton, S.W.

McArthur, W., 1, Gwydyr-houses, Brixton-rise, S.

Martley, W., 15, Cedars-road, Clapham-common, S.

Menge, Rev. J. P., Electrical-hall, Park-villas, Lower Norwood, S.

Milnes, William S., 11, Devonshire-road, Greenwich, S.E.

Monk, J. C., 3, Manor-road, Wallington, S.

Moren, George, 38, Threadneedle-street, E.C.

Painter, Henry, 1, Arlington-villas, Loughborough-park, Brixton, S.

Papengouth, Lieut. Oswald C., 12, Bloomsbury-sq., W.C. Price, Charles J., Carlton-chambers, Regent-street, S.W. Tefft, Benjamin F., LL.D., 31, Upper King-street, Holborn, W.C.

The Paper read was—

ON THE WEAR AND TEAR OF STEAM-BOILERS.

By FREDERICK ARTHUR PAGET, Esq., C.E.

According to the published report of the engineer of the Manchester Boiler Assurance Company, forty-three explosions, attended with a loss of seventy-four lives, occurred in 1864 in this country. The engineer of the Midland Boiler Assurance Company gives the number as forty-eight, causing the deaths of seventy-five and the injury of 120 persons. These statistics are confessedly incomplete, being, from obvious causes, numerically understated. The Royal Commissioners on the metallic mines report that, in the districts of Cornwall and Devon, boiler explosions are of very frequent occurrence;* and, in these sparsely populated districts, they easily escape the public attention. Explosions, again, which only injure without killing outright, and therefore do not call for a coroner's inquest, also happen without attracting much notice. The figures cited thus understate the destruction and injury to life through boiler explosions, while only a guess can be hazarded as to the annual loss of property they cause. Each explosion testifies to the probability that a number of boilers have been prevented from exploding by mere chance, as also to much unchecked decay and deterioration, which might have been prevented by greater care and more knowledge. Besides, apart from the disastrous results of an explosion itself, the undue wear and tear of boilers means the suspension of the workshop or factory and the demurrage of the steam-vessel. With respect to the causes of explosions themselves, "there are," to use the words of the late Mr. Robert Stephenson,† "but few cases which do not exhibit undue weakness in some part of the boiler;" and the same opinion appears to be held by Professor Faraday.‡ The opinion that an explosion is rather due to the weakness of the boiler than to the strength of the steam may in fact be said to be universal. There is, indeed, a very complex train of mechanical, chemical, and physico-chemical forces, leading to the deterioration and consequent destruction of a steam-boiler, and it is probable that no other metallic structure is subjected to such complicated conditions. The pressure of the steam and the heat of the fire produce mechanical effects, while both the burning fuel and the water react chemically on the plates and in accordance with their varying chemical properties. Each of these agents play, so to speak, into the other's hands, furthering and quickening the other's progress. It is difficult to distinguish with strictness between the effects of each; and it is mainly for the sake of convenient examination that they can be classified into:—1. The effects of the pressure of the steam; 2. the mechanical effects of the heat; 3. the chemical effects of the fuel; 4. the chemical effects of the feed-water.

THE DIRECT EFFECTS OF THE PRESSURE OF THE STEAM.

In calculating the working strength of a cylindrical boiler, the plates are assumed to be under a static load, and to be submitted to a tensile strain. The former of these assumptions is seldom, and the second is never

correct. There are two principal causes that tend to exert impulsive strains on the sides of a boiler:—1. The sudden checking of the current of steam on its way from the boiler to the cylinder; 2. quick firing, attended with too small a steam room; and both may sometimes be found to act in combination. To the first of these causes, the explosion, for instance, of one of the boilers of the *Parana* steamer, at Southampton, a few years ago, has been ascribed by the Government engineer surveyor;* to the second, the explosion of the copper boiler of the *Comie d'Es* yacht, in France. According to Dr. Joule, the mere pressure of an elastic fluid is due to the impact of innumerable atoms on the sides of the confining vessel. When the motion of a current of steam is suddenly checked, as by the valve in its passage from the boiler to the cylinder, its speed and weight cause a recoil on the sides of the boiler analogous to the effects of the, in this case, almost inelastic current of water in the hydraulic ram.† This action is necessarily most felt with engines in which the steam is let on suddenly, as in the Cornish and other single-acting engines, working with steam valves suddenly affording a wide outlet, and as suddenly closing. It produces such phenomena as the springing or braching of cylinder covers, and the sudden oscillations of gauges, noticed long ago by Mr. Josiah Parkes and others.‡ Some years ago, while standing on a boiler working a single-acting engine, and with a deficient amount of steam-room, the writer noticed the boiler to slightly breathe with every pulsation of the engine. The same action has been observed by others with boilers the steam-room of which is out of proportion to their heating surface. The intensity of the instantaneous impulses thus generated would be, as Mr. Parkes observes, difficult to measure, but their repeated action must rapidly affect the boiler at its mechanically weakest points. The more or less sudden closing of a safety-valve while the steam is blowing off would evidently produce the same effect; and this view is strengthened by the fact that the great majority of locomotive boilers—in which while at work there is no such sudden call on the reservoir of steam as in the Cornish engine—explode while standing with steam up at the stations.§ It is not denied that, in the case of a locomotive, the mere extra accumulation of steam from the safety-valves being screwed down above the working pressure will also come into play. But there can be little doubt that most boilers are subjected sooner or later, and with more or less frequency, to an impulsive load. This being the case, this consideration alone would demand a factor of safety of six in the designing of steam boilers. The Commissioners on the application of iron to railway structures, in their third conclusion on a mass of evidence which has made their investigations the most valuable ever conducted on the strength of materials, say:—"That, as it has been shown, that to resist the effects of reiterated flexure, iron should scarcely be allowed to suffer a deflection equal to one-third of its ultimate deflection, and since the deflection produced by a given load is increased by the effects of percussion, it is advisable that the greatest load in railway bridges, shall in no case exceed one-sixth of the weight which would break the beam when laid on at rest in the centre."||

Emerson showed, more than sixty years ago, that the stress tending to split in two an internally perfectly

‡ Proceedings of the Institution of Civil Engineers, 1852, p. 392.

cylindrical pipe, submitted to the pressure of a fluid from the interior, is as the diameter of the pipe and the fluid pressure. He also showed "that the stress arising from any pressure, upon any part, to split it longitudinally, transversely, or in any direction, is equal to the pressure upon a plane drawn perpendicular to the line of direction." As in a boiler the thickness of the metal is small compared with the radius, the circumferential tension has been assumed to be uniformly distributed; and the strain per unit of length upon the transverse circular joint being only half that upon the longitudinal joints, the strength of the latter has been taken as the basis of the calculations for the tensile strength of the joints. But in taking the internal diameter of the boiler as the point of departure, the internal section has been assumed to be a correct circle, which would only be practically true in the case of a cylinder bored out on a lathe, and never in that of a boiler. Two of Emerson's corollaries from his first proposition have in fact been neglected. He shows that if one of the diameters be greater than another, there will then be a greater pressure in a direction at right angles to the larger diameter; the greatest pressure tending to drive out the narrower sides till a mathematically true circle is formed. The second is that, "if an elastic compressed fluid be enclosed in a vessel, flexible, and capable of being distended every way, it will form itself into a sphere." A number of proofs can be adduced that both these influences are more or less at the bottom of the wear and tear caused by the direct action of the steam.

From 1850 to 1864 forty locomotive explosions causing a loss of human life have occurred in the United Kingdom. The Board of Trade reports in the Bluebooks presented to Parliament, and more especially those by Captain Tyler, R.E., probably form the most valuable and connected series of records extant on boiler explosions. This is more especially the case with regard to wear and tear caused by the direct action of steam unmasked by the effects of the fire, as the barrel and outside fire-box of a locomotive cannot be said to be under the direct action of the heat. Perhaps the vibration of the boiler through the motion on the line may intensify this action, but it is clear that vibration cannot be a primary cause. The majority of the reports are illustrated by careful drawings. Eighteen of the forty boilers gave way at the fire-box—eleven from the crown of the inside fire-box being blown down upon the tube plates; seven from the shells or sides giving way. Twenty burst at the barrel; and two explosions may be ascribed to miscellaneous causes, from an originally defective plate, and from running off the line. Leaving out all those which occurred at the fire-box, as the majority of these might be ascribed to other influences than direct pressure, all the twenty explosions of the barrel could be traced either to internal furrows or to cracks, both running parallel with one of the longitudinal joints of one of the rings forming the barrel. All the joints which thus gave way were lap-joints; and the furrows or the cracks (and the former greatly preponderate in number) occur at the edge of the inside over-lap, and, therefore, just at the point where the diminution of diameter caused by the lap-joint would be most affected by the pressure of the steam. (See Fig. 1.)

The plate at the channels shows distinct traces of lamination through the cross-bending, and it is probable that plate of a good material will gradually laminate, while

* The action of a fluid pressing with equal forces in all directions can be evidently represented as to force and direction by innumerable radii of equal length led from a single point in all directions. Upon this principle may be explained the spherical shapes of soap bubbles, of the bulbs of thermometers (blown while the glass was in a plastic state), of the thin india rubber balls, used as playthings, and which are formed by forcing air into india rubber tubes closed at one end. Gas and air bubbles in water are necessarily flattened by the hydrostatic pressure. It is upon that principle that a gun of soft ductile iron often bulges out at the breech.

FIG. 1.

(Full size cross section of the furrowed longitudinal joint in the fire box ring of a boiler which exploded at Overton station, on the 30th May, 1864. It does not differ from other furrows.)

inferior metal will crack through in much less time. Nor are these furrows found with only lap-joints. Butt-joints, with a strip inside the boiler, and thus destroying the equilibrium of internal pressure, have been found to be attended with similar furrows. Channels of exactly the same character have been observed in locomotive boilers with lap-joints, which have exploded in Germany.*

Similar furrows, again, have been noticed in marine boilers, and in old boilers generally, longitudinal furrows being of course about twice as dangerous as those appearing transversely. The smoke-box tube-plates of inside cylinder-locomotive engines have been found to be similarly influenced by the racking action of the engines, showing furrows around the cylinder flanges. A parallel case is often found in Lancashire with the end-plates of double-fueled Fairbairn boilers, which may have been too stiffly stayed to the barrel. Circular furrows, caused by the confined motion of the end-plates are sometimes found at the base of the angle iron rings joining the internal flues to the end-plates. But furrowing seems with no kind of boiler to be more felt than with locomotive boilers. This is due to the higher pressure, to the thicker plates causing a coarser lap, and more especially to the fact that the unstayed barrel cannot be thoroughly examined without drawing the tubes, thereby enabling the furrow to enlarge itself unnoticed.

The inside fibres of a plate bent up while cold are necessarily initially in a state of compression. When the pressure from the inside comes on, striving to form a perfect cylinder, the plate gets bent to and fro by its own

* Organ fuer die Fortschritte des Eisenbahnwesens. 1864, p. 150.

elasticity on one side, and by the pressure on the other. If the iron be brittle, it may crack right through; if ductile, the outside fibres gradually lose their elasticity, and, necessarily aided by other causes, crack away. This action is progressive, and probably very rapid towards its later stages. Once a weak place formed itself it would have to do more and more of the work. Even when pulled by the direct tension of the testing machine, a lap-joint behaves in a somewhat similar way. For instance, a half-inch lap, solidly welded by Bertram's process, has only half the strength of the solid plate;* while the $\frac{3}{4}$ inch lap-weld has actually two-thirds of the strength of the entire plate.

Messieurs Jean Piedboeuf and Cie., of Aix-la-Chapelle, Düsseldorf, and Liege, who turn out annually upwards of one thousand steam boilers, use a lap-joint which probably gives slightly better results as to furrowing, while it is much easier to caulk, and must be therefore less injured by that process. (See Fig. 2.)

FIG 2.

(The edges of the plates are cut to an angle of 66° by means of inclined shears.)

There is, however, another important appearance to be noted with respect to these furrows. An iron cylindrical vessel under internal pressure would of course rupture long before it could assume a spherical shape, from its ranges of elasticity and of ductility being so short. But it may be said to be undergoing three distinct stresses in as many directions. There is a stress acting on the ends, and tending to rupture the boiler in two halves in a direction parallel to the axis; there is the stress which is hoop tension in a true circle, but which acts with a cross-bending strain in an ordinary boiler; and there is the stress which tends to make it assume the shape of a barrel, or to bulge it out in the centre of its length. The precise action on a material of several strains like this is a portion of the strength of materials which is still completely unknown. Its probable effects might be illustrated by the ease with which a stretched india-rubber ring is cut

through with a knife, or that with which a column under compression is broken by a blow from a hammer, or by the similar ease with which a tube under tension is split by a sharp blow; in fact, the operation of caulking a defective boiler under steam seems thus to often give the finishing stroke which causes an explosion. The boiler which burst from a defective plate at the Atlas Works, Manchester, in 1858, and that which burst through a crack at a longitudinal joint last January, at Peasebrough, both gave way whilst being caulked. This accounts for the fact that adjacent boilers sometimes explode one after the other, pointing, at the same time to the danger into which a sound boiler may be thrown by an explosion. Upon the same principle it is probable that the modern guns, built up from strained rings, will be easily put *hors de combat* by shot. The probability is that a number of simultaneous strains in different directions diminish the elasticity of the material that would allow it to yield in any given direction. However that may be, it will be seen that it is only the pressure on the ends of the boiler acting parallel to the axis, and tending to tear the cylinder through transversely, which bears heavily on the rivetted joint, or rather on that metal between the rivets which is left after punching to the metal at the over-lap. With respect to the stress tending to burst the cylinder in the centre, it is clear that if we suppose a strip cut out from the entire length of the boiler, each portion of the length of this strip could be regarded as a beam under an uniformly distributed load. As, however, with the lap joint, there is a double thickness of metal transversely, that joint is the strongest and suffices to resist the stresses tending to bulge out the cylinder in the middle, and also to tear it into two halves. This affords some justification for the belief of old boiler-makers, before rivetted joints were tried under a direct tensional load, that the joints are the strongest parts of the boiler. And, indeed, this is what we find in practice. The thinnest portion of the longitudinal furrows is generally exactly in the middle of the plate, and this is caused by the longitudinal stress, which is acting at right angles to the transverse cross-bending stress. A strip cut from joint to joint is, in one respect, in the condition of a beam supported at both ends, uniformly loaded throughout its length, and, according to known principles, therefore giving way in the middle. (See Fig. 3.)

The middle ring of the boiler which burst at the Metropolitan Railway last year, and the fragments of which were examined by the writer, also first given way at a furrow. Captain Tyler reports that at from 16 $\frac{1}{2}$ to 19 inches from the transverse joint, or just about the middle of the plate, there was "very little metal left holding," while it gradually got to its original thickness of $\frac{3}{4}$ as the groove receded from the centre of the plate and towards the transverse joints at each side.

It is impossible to deny the existence of an infinite number of stresses acting on the sides of a vessel undergoing fluid pressure, producing what, for want of a better term, might be called a "bulging strain." Instances of the action may be noticed in the sketch of the leaden pipes given by Mr. Fairbairn,* which were bulged out in the middle by internal pressure, as also in the fire-box sheet influenced by the same means, and in the centre of the surface. Unaccountably enough, the effect of such a strain on the ultimate resistance, and, above all, the elasticity, of materials, has been entirely neglected by investigators, and there are no published data on the matter. The effect of the internal pressure is evidently resisted by a double thickness of plate at the joints, so

Fig. 3.

(From Captain Tyler's report, dated 30th June, 1864, on the boiler explosion at the Overton station of the London and North-Western Railway. The plate torn off is shaded, the course of fracture on the other side of the boiler is dotted, while the furrow is shown by the thick horizontal line.)

that the load on the middle of a single ring may be considered as determining the weakest part of the boiler. One of the rings of the Great Northern boiler which exploded on the Metropolitan Railway last May had a length transversely of about (say) 36 inches from lap to lap, with an inside diameter of 45 inches. If we now suppose a strip one inch broad cut from the 36 inch long plate, parallel to the longitudinal axis of the boiler, this strip is, supposing there be a pressure of 100 lbs. to the square inch, uniformly loaded with 3,600 lbs.—equal to a transverse load of 1,800 lbs. at the centre. Supposing the plate to form a true circle, a hoop one inch wide of the $\frac{1}{2}$ plate would be subjected, circumferentially, to a tensile load of 6,000 lbs. per square inch, while (leaving out the diminution of area at the ends through the flue tubes) each portion of the circle, about 1 inch broad and $\frac{1}{2}$ inch thick, is subjected to a load of about 1,125 lbs. acting parallel to the axis of the boiler.

To construct a general rule or formula that would take into account the distorting effects of the lap or of the welt of butt-joints would be impracticable; but it is clear that the usual mode of calculating the strength of a cylindrical boiler from the tensile strength of joints tested by weights, or hydraulic pressure, directly applied, is far from being correct. It is only tolerably correct with scarf welded joints, or with butt joints with outside welts. Even here, the hoop tension of the true cylinder is resolved into a cross bending strain, if the cylinder does not form a correct circle internally. The usual formula would be practically correct, if the boiler were prevented from altering its shape during the impulses sometimes given by the steam, and the quieter buckling action caused by the alternate increase and fall of the pressure. In fact a boiler, like a girder, does not merely demand a high ultimate strength, but also a stiffness which is the protection against alternative strains—against buckling or collapse.

Disregarding the effects of the thickness of the material, a perfect cylinder should theoretically afford the same ultimate resistance, whether exposed to external or internal pressure. Its resistance to collapse should indeed be greater, as most materials give more resistance to compression than to tension. This is not the case, as the distortion of form progressively weakens an internal

flue, by increasing the load on its surface, while the contrary is rather the case with the boiler exposed to internal tension. Before Mr. Fairbairn showed the inherent weakness of flue tubes, their frequent explosions through collapse were ascribed to spheroidal ebullition and other similar causes. They are now, according to the engineer of the Manchester Boiler Association, stronger than the shells, by means of the T-iron and angle-iron bands now generally used, and also by the excellent seams introduced by Mr. Adamson so long ago as 1852.* While T-iron and other bands could be used for the barrels of boilers not exposed to the fire (as is recommended in France† and by the Board of Trade Inspector of Railways), Adamson's seams reversed would probably form excellent transverse joints for a shell fired from the outside, and, with a boiler like this, thin and narrow plates could be used, affording a stronger and tighter lap-joint. With a construction of this kind little or no deflection or bulging could occur, and the sectional area of the plate and the rings would really give the strength of the boiler.

2.—THE MECHANICAL EFFECTS OF THE HEAT.

While a maximum of stiffness to the mechanical action of the pressure is required in a steam boiler, a maximum of flexibility to the irresistible mechanical force of heat is of no less importance. For instance, a great advantage of some of the forms of strengthening rings for internal flues is that they allow the use of thinner plates; together forming a structure of great flexibility to complicated thermal influences. The longitudinal expansion of inside flues like this is taken up by a slight spring or swagging at each joint, and the end plates of the shell are not unduly strained by the combined efforts of the internal pressure and the expansion due to heat. This is one way in which defective circulation, or a sudden current of cold air or of water, can act on the structure, by unequally straining the plates; and, although it seems probable that the effects said to have been thus produced, are, to some extent, due to other causes, they point to the importance of keeping the temperature of the plates as low as possible. One protection against effects of this kind is the gradual diffusion of heat, produced by its conduction to and from the different plates. It is a general belief with engineers that a pressure of steam strains a boiler more than cold hydraulic pressure; but it is unsettled as to what amount and in what exact way. The basis of an examination of the kind would have to be sought in an exact determination of the temperature of a plate which is transmitting the heat to the water, and this has not yet been determined with any accuracy. The fact is, as is remarked by M. Péciot, who has given great attention to these questions, the different phenomena involved are extremely complicated. It is clear that the plates must always be at a higher temperature than the water, as it is by the difference of temperature of the two surfaces of the plate that it is traversed by the heat. He supposes that, though the flow of heat through the plate is inversely as its thickness (while it is directly as the surface and as the difference of temperature between the outside and inside faces), yet the flow of heat would be the same through a thicker plate, from the greater difference of temperature between the two surfaces.‡ He does not seem, however, to be aware of the important law demonstrated by Mr. J. D. Forbes, that the conducting power of, for instance, wrought iron, rapidly diminishes at the higher temperatures. At 200° C. it has little more than one-half the conducting power it has at 0°.§ At yet higher temperatures it might probably be proved, if an applicable instru-

§ Royal Society of Edinburgh, 28th April, 1862. "Experimental Inquiry into the Laws of the Conduction of Heat in Bars, and into the Conducting Power of Wrought Iron."

ment for registering higher temperatures were in existence, that the powers of conduction are still less. Some of Mr. Peclet's experiments also seem to be vitiated by his disregard of Dr. Joule's discovery that water is heated by being mechanically stirred up. It is, however, certain that water can only moisten a metallic plate when at a lower temperature than 171°C . As soon as the water gets thus repelled, the heat radiated by the metal is reflected back from the surface of the liquid; the metal gets hotter and hotter, with a corresponding diminution of its conducting powers; its outside, exposed to the fire, would more or less oxidise, and with a similar result; and a like effect is produced on the inside—on the roughened surface of which incrustation would rapidly adhere, forming a calcareous coating, conducting with about sixteen times less power than iron.* All these tendencies are of a progressive character, leading to very high temperatures in the plate, even to a red-heat. This tends to explain how rivet-heads close to the fire are soon burnt away by the friction of the current of heated gases on the red-hot metal; how thick fire-boxes are sooner burnt out than lighter ones, the process being often arrested at a certain thickness; how internal flues of thick plates so often give trouble; how externally fired boilers are most deteriorated at the corners from the junction of the three plates; and similar results well known to practical men. Another proof that thin plates conduct more heat than thick plates is afforded by some experiments lately made in Prussia, with two egg-end boilers, exactly similar in every respect, except that one was constructed of steel plate $\frac{1}{2}$ inch, while the other was of wrought-iron about $\frac{3}{4}$ inch thick. The steam generating power of the steel boiler was to that of iron as 127.49 to 100†—a result which can only be accounted for by the relative thickness of the plates. Thick plates are also more liable to blisters, one of which would considerably diminish the conducting power of the spot where it happened to form.

While it is certain that boiler plates can assume very high temperatures, even up to red-heat, authorities differ as to the diminution of ultimate strength which is caused by heat, while its effect on the elasticity of the plate has been scarcely attended to. The experiments on the ultimate tenacity of iron at high temperatures, conducted by Baudrimont,‡ Seguin, and the Franklin Institute, can scarcely be looked upon as of much value, for they were made on a very small scale, and with no regard to the temporary and permanent elongations—or to the effect of heat on the elasticity and ductility.

Mr. Fairbairn§ observed no effect on the strength of plate iron up to almost 400°F . At a "scarcely red" heat the breaking weight of plates was reduced to 16.978 tons from 21 tons at 60°F .; while at a "dull red" it was only 18.621 tons. MM. Tréméry and P. Saint Brice,|| aided by the celebrated Cagniard Latour, found that at nominally the same temperature (*rouge sombre*), a bar of iron was reduced in strength to one-sixth of its strength when cold. This is much greater diminution of strength than that found by Mr. Fairbairn. Apart from other causes, this might easily be due to the fact that incandescent iron affords a different tinge during a dull day to what it does in a clear light. In fact, the great impediment to all these investigations is the want of a thermometer for high temperatures; but M. Tréméry's result is perhaps more conformable with daily experience. Mr. Fairbairn's data would show that the ultimate strength of wrought iron is reduced to about one-half; but M. Tréméry's result explains the generally instantaneous collapse of flues when

red-hot, and which have been of course originally calculated to a factor of safety of six.

A most important question is the effect of temperatures, whether high or low, on the elasticity of the material—whether iron will take a permanent set with greater facility at a high temperature? These data are really more important than those on the ultimate strength, as they would show the influence of temperature on the elastic limit. Here again is a vacancy in existing knowledge, which can scarcely be said to be filled up by the few experiments of the late M. Wertheim on very small wires.* He found, however, that the elasticity of small steel and iron wire "increases from 15°C to 100° , but at 200° it is not merely less than at 100° , but sometimes even less than at the ordinary temperature."

There is, however, another very important point with respect to wrought iron, which has scarcely received the attention it deserves. As would appear from a number of phenomena, there seems to be a sort of thermal elastic limit with iron. When heated, and when its consequent dilatation of volume does not exceed that which corresponds to (perhaps) boiling point, it returns to its original dimensions. Beyond a certain temperature it does not contract again to its pristine volume, but takes a permanent dilatation in consequence, apparently, of its elastic limits having been exceeded. A number of observers have determined the fact with cast iron, and though wrought iron has not been expressly investigated in this direction, there is no doubt that it exhibits a similar behaviour. Thus, a number of years ago,† an Austrian engineer, named C. Kohn, remarked that a boiler about 12 metres long and 1.67 in diameter, with a thickness of plate of 0.011, permanently expanded, at a temperature corresponding to a steam pressure of 5 atmospheres. (153°C .) by 0.07198, and did not, when cold, return to its original dimensions. The same thing has been noticed, by means of very accurate measurements, with other boilers. A number of experiments by Lt.-Col. H. Clerk, of Woolwich, on wrought iron cylinders and plates,§ bear distinct evidence to a dilatation of volume in wrought iron, when repeatedly heated and suddenly cooled. In experiment 7, for instance, "two flat pieces of wrought iron, each 12 inches long, 6 inches deep, and $\frac{1}{2}$ inch thick, were heated and cooled twenty times, one being immersed to half, and the other to two-thirds, its depth in water. That immersed one-half contracted or became indented on the ends fully .3 inch; the other had similar indentations, but only to one-half the amount. They both turned up into the form of an arc," the convex side of which appeared in the portion heated and cooled. Unfortunately, the specific gravities of the different portions were not tried by Colonel Clerk. A succession of trials of the kind produced cracks in the metal, thus explaining how boiler plates are cracked by imperfect circulation and by cold feed-water let in near the fire; and, the thicker the plate, the more permanent dilatation of volume and consequent danger. Mr. Kirkaldy found that "iron highly heated and suddenly cooled in water, is hardened," being injured, in fact, if not afterwards hammered or rolled. This permanent dilatation of volume must be necessarily accompanied with a diminution of specific gravity, thus affording another close analogy between straining iron by loads in excess of the mechanical elastic limits, and straining by heat. Lärjehelm, found long ago that the specific gravity of iron is diminished by strains in excess of the limit of elasticity, and this result has been completely confirmed by Mr. Kirkaldy's numerous experiments. The smith calls iron "burnt" which has been rendered brittle in working through the often repeated applications of heat, or through

too high a temperature. Iron rendered brittle by strains in excess of the limit of elasticity has been long popularly termed "crystallized." Both these states are accompanied with a dilatation of volume and attendant hardness and brittleness, and both seem to be referable to very similar causes. In fact, a very general belief exists that very ductile good iron, used in the form of a steam boiler, soon gets brittle. There are some applications of metal to a steam boiler peculiarly liable to be strained beyond the limits of elasticity; by mechanical force, by the mechanical force of expansion and contraction, and by dilatation of volume through heat all three acting simultaneously. Such is the case with fire-box stay-bolts. Accordingly, they are found to get very brittle when of wrought iron—which is a much less ductile metal than copper. Mr. Z. Colburn states that he has "frequently found these stays (where made of wrought iron) to be as brittle, after a few years' use, as coarse cast iron." He has "broken them off from the sides of old fire-boxes, sometimes with a blow no harder than would be required to break a peach-stone."

3.—THE CHEMICAL EFFECTS OF THE INCANDESCENT FUEL.

Whatever physical changes may be induced in iron by the long continuance of a high temperature which is not succeeded by the application of the impact of the hammer or the pressure of the rolls, it is certain that long-continued red heat leads to the loss of its metallic consistency. Its surface gets converted to a greater or less depth into large scales, which, according to Berthier, consist of a crystallized compound of peroxide and protoxide of iron. The mechanical action of the gases—and especially of the free oxygen contained in every flame—forced at a high velocity by the draught past the more or less heated plates, would also aid these chemical combinations—upon the same principle as iron filings, thrown through a gas flame, burn in the air; and upon the same mechanical principle as the incandescent lime is worn away by the flame of the oxyhydrogen blow-pipe. These actions would take place with any fuel, even with pure charcoal. But when mineral fuel, which mostly contains more or less iron pyrites, is used, there is much more danger to the plates, especially over the fire, in getting red hot, as the flames would then hold sulphurous acid, and often volatilised sulphur. A familiar illustration of an action of this kind is afforded by the fact that a piece of red-hot iron plate can be easily bored through by means of a stick of sulphur, the combination forming sulphide of iron. Dr. Schafhaeuti, of Munich, has given great attention to the changes in plates subjected to the action of fire; twenty-five years ago he read a paper before the Institution of Civil Engineers,† and more recently he has published an essay, both on this subject, in a Munich periodical.‡ He has brought forward a number of facts, founded on chemical analyses of plates of exploded boilers, showing the danger, due to chemical action alone, when the plates of a boiler become red hot. He notices that the iron of the inside of the plates, in getting red-hot, decomposes the water, and combines with the oxygen thus freed. It also loses some of its carbon. The outside combines with the free oxygen and with any sulphurous acid in the flame. He states that iron made with pit coal is much more affected than charcoal-made iron; becoming laminated at the original joints in the pile out of which the plate has been rolled. It is possible that portions of oxide are carried into these joints, and it is at any rate certain that iron gives way easiest at these places. This points to the great value of really homogeneous plates, such as those of cast steel, in which homogeneity has been obtained by the only known means of fusion.

The remarkable diminution of elasticity and of tenacity caused by the combination of the red hot iron with sulphur; the absence of all elasticity and tenacity in the oxides of iron, show that, even if a flue do not at once collapse, or a shell explode, through getting red-hot, the boiler is more or less injured every time it gets overheated. A defective circulation, by permitting such a temperature as to drive the water off the plate, would soon lead to local injury. Particular spots in externally fired cylindrical boilers are sometimes, as is stated by Mr. L. Fletcher of Manchester, thus affected, and in an apparently mysterious way. A new boiler in which a heap of rags were accidentally forgotten, had the spot burnt out in a few days,* doubtless through the resulting defective circulation and its consequences. The plates just above the fire of internal flues also suffer in this manner. It is perhaps possible that turned joints, secured by bolts, and allowing an occasional reversing, or rather rotating, of the ring, might, in some cases, be here of service. At any rate, universal experience proves that the thicker the plate the easier does it get red hot; and these chemical facts also point to the desirability of a minimum of thickness. In fact, the wearing away of the plates through these causes, if mechanically strong against pressure, often gets arrested at a certain thickness. In Germany and France, some of the best manufacturers still make the plates over the fire of, for instance, inside flues, slightly thicker than anywhere else; but the combined chemical and mechanical actions of the heated fuel cause most wear and tear in a thick plate, and thus justify American practice in this respect. In that country, fire-box plates of good charcoal iron are made only $\frac{1}{8}$ or $\frac{1}{4}$ of an inch thick, and, with stays four inches apart, give good results under nearly 150 lbs. steam pressure.

4. THE CHEMICAL AND PHYSICO-CHEMICAL EFFECTS OF THE FEED-WATER.

The wear and tear of a boiler which occurs in the form of corrosion, properly so-called, may be divided into two principal kinds:—(1.) Internal, and (2.) external. The progress of both is necessarily intensified by the mere effects of temperature; each, however, has its strongly-marked, distinct character—not merely as to position, but also as to origin and results.

A steam boiler is in the position of a vessel into which large volumes of water are continually forced; while the heat applied, driving off all volatilizable matter, leaves behind a concentrated solution with a chemical character dependent on that of unvolatilizable matters in the feed-water. The specific gravity of the substances found in the water naturally causes them to sink towards the bottom, at which part the solution is generally more concentrated, however much it may be stirred up by the ebullition. Mr. J. R. Napier lately stated that a piece of zinc "about four feet long, by three inches broad, by three-sixteenths thick, placed in a marine boiler for three weeks" to a depth of 18 inches in the water, showed a corrosion which rapidly decreased "up to the highest part," which, in the steam, appeared to be little affected.† This accounts for the fact that all boilers, even those internally fired, like locomotive boilers, have their plates most affected towards the bottom, and that internal corrosion always shows itself to a greater extent below the water line. The *bouilleur* of the form of boiler known as the French boiler is also generally more affected than any other part. To resist this sort of slow action, it is clear that the more the bulk of metal the better, and it is for this reason that the bottom plates of most marine boilers are made thicker, while these same plates in locomotive boilers have to be often renewed. Any chemical or physico-chemical action of the kind is of course intensified by temperature, and this is one of the causes why externally fired boilers give way most a little in front of

* Steam Boiler Explosions, 1860, p. 32.

the furnace. But the plates above the water-line also get more or less corroded, and not merely with the usual character of rusting, but in that peculiar form known as pitting, which generally shows itself much more strongly marked below the water-line.

The presence of a concentrated solution of an acid or alkaline character, kept at a high temperature for years in contact with iron plates, would be sufficient to account for much corrosion. But the internal corrosion of steam boilers has many features of such a mysterious character, that no accredited explanation of its attendant phenomena has yet been put forward. In the first place, plates thus attacked show a number of irregular holes like a pock-marked human face, or like the small craters seen on the moon's surface. (See Fig. 4.) The writer has

Fig. 4.

(The internal surface of a plate of an old wrought iron boiler, showing, one-quarter of the full size, the ordinary appearance of pitting.)

also sometimes observed two or three little irregular excavations like this in a plate otherwise showing a large surface quite intact. Sometimes the plate is most pitted round a projecting bolt; at others, one plate will be perfectly sound, while that rivetted to it will be almost eaten away, both having been the same time at work, and under, of course, apparently exactly similar conditions. With locomotive boilers this pitting has been ascribed to galvanic action between the brass tubes and the iron plates. But it is notoriously well-known to locomotive superintendents, that boilers with iron tubes are often worse pitted than those which have run the same distance with brass tubes. Besides, all iron boilers, with or without brass, whether used for stationary, locomotive, or marine, purposes, are subject to pitting.

An explanation which seems to meet all the circumstances of the case is the following:—Mr. Mallet, in a report addressed to the British Association some years ago, showed that wrought iron and steel (blister steel probably), "consist of two or more different chemical compounds, coherent and interlaced, of which one is electro negative to the other." In fact ordinary wrought iron, being also welded up from differently worked scrap, is far from being an electro-homogeneous body. In a boiler, the hot water, more or less saturated with chemical compounds, is the exciting liquid, and the electro-positive portions of the plates are thus quickly removed to a greater or less depth. This explanation meets most of the known circumstances with respect to pitting; it even, in a great measure, ex-

plains how plates above the level of the water, especially in marine boilers, get very rapidly corroded in portions, while another part of perhaps the same plate is scarcely affected. The concentrated water in a marine boiler is known to be generally acid. "Of all the salts contained in sea-water," says Faraday, "the chloride of magnesium is that which acts most powerfully" on the plates. He shows that a cubic foot of sea-water contains 3·28 oz. of this salt, and, at the same time, points to the danger of voltaic action in a boiler through the contact of copper and iron. In a smaller degree the contact of cast with wrought iron, or between the different makes of wrought iron in the same plate, or between contiguous plates, acts in the same way. It is not improbable that some hydrochloric acid is present in the steam of marine boilers. "Mr. J. C. Forester has tested some of the condensed steam from the safety-valve casing, and from the cylinder-jacket of the Lancashire, and found both decidedly acid."† With an exciting liquid in the condensed steam, it is thus explicable how the plates of marine boilers often get corroded in a most capricious manner; while, at the same time, the current of steam would create a certain amount of friction on the oxide, clearing it away to act on a fresh surface.

The crucial test of this explanation of pitting would be the observation of the absence of the phenomenon from plates of an electro-homogeneous character. This homogeneity could only be expected from fused metal, such as cast-steel. Accordingly, while the writer was in Vienna a short time ago, he was assured by Mr. Haswell, the manager of the Staatsbahn Locomotive Works, that some locomotives made of cast steel plates in 1859, for the Austrian Staatsbahn, had been working ever since without showing signs of pitting, though under similar conditions iron plates had severely suffered in this way. Pitting may thus be fairly defined as a form of corrosion localised to particular spots by voltaic action. It is also probably aggravated through the motion of the plate by mechanical action, and the expansions and contractions through alternations of temperature. All boilers are most pitted near the inlet for the feed water, and with inside cylinder locomotive boilers there is generally more pitting at the smoke-box end—no doubt caused by the more or less racking action on these plates. A state of corrosion at particular spots would probably be kept up to a greater intensity by the incrustation being mechanically thrown off. With a quicker voltaic action, caused by any unusual intensity of the exciting liquid, the sides of the cavities in the plates would be sharper and less rounded off; as in the case of the boiler fed with mineral water from ironstone workings, which exploded last year at Aberaman, South Wales. (See Fig. 5.)

The fact that pitting occurs in marine boilers when distilled water from surface condensers is used, does not affect this explanation. Water distilled in this way, from whatever cause, after repeated boiling, is stated to carry the salinometer even higher than sea water, thus proving that it is not pure‡. In the next, there is the absence of incrustation, which to some extent always protects the plates of boilers from the chemical action of its contents. In this way the mechanical buckling of the plates,—directly and indirectly causing the furrows we have spoken of,—by continually clearing particular lines of surface from incrustation and oxide, reduces these particular spots, with respect to corrosion, to the condition of the plates of a boiler fed with water which deposits no incrustation. Corrosion will also

FIG. 5.

(From a photograph of surface of corroded plate cut from one of the two boilers that exploded on Wednesday, February 17th, 1864, at Aberaman Iron Works, Aberdare. The corrosion was internal, and in some parts the plate was not more than one-eighth thick. Thirteen persons were killed, and many others seriously injured.)

act more rapidly at a furrow through mere increase and renewal of surface. To resist that form of internal corrosion specially known under the name of pitting, a maximum of electro-homogeneity is evidently required in all the component parts of the boiler.

While the action of internal corrosion, often very equally corrugating the plates over a large surface, as a rule scarcely, at any rate only gradually, affects their mechanical strength, external corrosion, being localized to particular spots, is of a much more dangerous character. The one is gradual and easily perceptible, while the other is rapid and insidious in its progress. Apart from accidental circumstances affecting the brickwork on which a stationary boiler is erected, or the outside of the bottoms of marine boilers, it is clear that external corrosion can only occur through leakage. When leakage takes place through a crack in the plate caused by mechanical action, or at a hole burnt out by heat, the effects of leakage are only secondary results, due to a primary cause which of itself may cause the stoppage of the steam generator. But a leakage at a joint may in itself gradually cause the destruction of the boiler. Here we see another reason that the character of a boiler, not merely as to ultimate strength, but also as to wear and tear, intimately depends upon the form of its joints. It is often noticeable that very good lap joints, even when tested under hydraulic pressure up to only 50 per cent. above the working load, sweat more or less. The tendency of the internal pressure to form a correct circle bears indirectly on these joints, causing them to open, more or less, and to leak, in spite of the caulking. Mr. Robert Galloway, C.E., who, as an Engineer Surveyor of long standing of the Board of Trade, has probably made more than three thousand careful inspections of marine boilers, states that he has often noticed a furrow or channel on the outside of the joint, running parallel to the outside overlap for some distance, and evidently caused by leakage. Along the water line, condensed water will act on the joints, while below it the concentrated contents of the boiler will come into chemical action

A leakage in a marine boiler often eats away a plate within a year. In some cases a jet of hot water from a leakage has a frictional action; in fact, even with such an incompressible and hard substance as glass an effect like this has been perceived, and a slight leakage continued during several days sometimes produces a noticeable furrow on a glass-gauge tube. With sulphurous fuel, a powerful chemical-action will come into play on the plates. One volume of water taken up about thirty volumes of sulphurous acid gas; and these sulphurous fumes of the fuel, coming into contact with the water from a leakage, will be more or less absorbed. An acid solution like this must quickly eat away the plate. It is certain that a leakage acts much quicker on a boiler fired with sulphurous fuel than on one fired with wood. M. G. Adolphe Hirn has observed a plate, nearly seven-eighths thick, to be pierced, in the course of time, as with a drill, by means of a little jet which struck it after passing through a current of hot coal smoke.*

LEGISLATIVE ENACTMENTS.

No stronger proof can be adduced of the empirical state of existing knowledge of the management of boilers than that afforded by a consideration of their average duration. While some marine boilers last only about three years, there are carefully worked land boilers which have lasted as long as thirty. Captain Tyler, R.E., estimates the average duration of a locomotive boiler at from five to twenty years. Perhaps the average duration of a marine boiler may be reckoned at from five to seven years; that of a locomotive boiler at from eight to nine years; that of a stationary boiler at from eighteen to twenty years—all being supposed to be fairly worked under ordinary conditions.

It is clear that, subjected as a steam boiler is to so many destructive influences, the precise effects of which can scarcely be yet very accurately known, the working tension should be only one-eighth of the ultimate bursting strength. But when boilers, as is too often the case in England, are bought by the weight; when cheaply paid labour is employed in their management; when inspection of the progress of the wear and tear necessarily happening even with good boilers and good attendance, is precluded for the sake of gain, there is then a suit of expense versus risk, in which parsimony too often gains the day. At any rate, a number of painful accidents in all parts of the world have, at different times, pointed to the fact, that every man picked at hap-hazard cannot be safely trusted with steam-power. In fact, there is probably no civilized country in which the legislature has not more or less interfered in the management of steam boilers. In the States of America, the frequency of boiler explosions has in some localities produced a more despotic interference than perhaps anywhere else. In the city of New York, boilers are under the supervision of the municipal police; they are tested periodically; and, as a result, many are condemned every year. By an enactment of Congress, applicable to all the States,† steam passenger vessels are subjected to Government inspection. The 13th section of this Act shows a very acute perception of the real cause of a boiler explosion, "which," it states, "shall be taken as full *prima facie* evidence" of negligence on the part of the owner, upon whom is thus put the onus of disproof. The law of Louisiana‡ is particularly severe, requiring the application of a hydraulic test threefold that of the working pressure. Of course, there is a great distinction between enacting a law and putting it into practical execution, and it is probable that laws like these could only be carried out by organized bodies of police, like those on the continent. In France, in 1810, 1825, 1828, 1829, 1830, 1843, and

* Bulletin de la Société Industrielle de Mulhouse, 1861, p. 553.

† Session of Congress, July 7, 1838.

‡ Baltimore American, 1835.

lastly on the 25th of January, 1865, as many different regulations have been issued with respect to steam boilers of all kinds. Beginning by requiring that every boiler, even of wrought iron, should be submitted to a hydraulic test of five times the working pressure, this has been successively lowered down to a threefold pressure in 1843, and lastly to a twofold pressure, by the Imperial decree of this year.* The previous law fixed the minimum thickness of the plates—a regulation which undoubtedly did much injury to boiler making in France. The old Prussian regulation of the 6th of May, 1838, also fixed the thicknesses of the plates, but did not require any hydraulic test. By the *Régulation*† of the 31st of August, 1861, this was completely altered. The construction of the boiler was left entirely in the hands of the maker; but stationary boilers had to withstand a threefold, and locomotive boilers a twofold, hydraulic pressure. In the same way as with the present French law, the test had to be repeated after any considerable repairs. On the 5th of March, 1863, a ministerial decree reduced the testing pressure for old locomotive boilers down to $1\frac{1}{2}$ of the working pressure; and another *Circular Erlasse*, published on the 1st of December, 1864, reduced the test for all kinds of boilers down to twice the working load. There is now no material difference between the French and the Prussian regulations respecting boilers; and it may be expected that those continental states, such as Russia, Switzerland, and Spain, which have more or less copied the old French law of 1843, will also adopt the present alterations. There is also some talk about altering the present Austrian law,‡ which determines the thickness of the plates, but only demands a double pressure test. The Belgian *règlement* § also requires double the working pressure for common boilers, but only $1\frac{1}{2}$ for tubular boilers. According to Article 31, the test must be annually applied to locomotive, portable, and marine boilers, as also after all considerable repairs. There does not seem to be any general law in Italy, but in the special acts authorizing railway companies, similar requirements to the French regulations are laid down, and government commissioners see that they are carried out. Each of the smaller German states also has its law, more or less like that of France and Prussia. Mecklenburg-Strelitz|| requires that common boilers be proved to three, and tubular boilers to twice the working pressure; to be renewed every fourth year, and every time that the boiler is repaired or altered; Saxony,¶ that cylindrical boilers be tried to twice the working pressure, and tubular boilers to a pressure three atmospheres above it. Bavaria** now requires double the working power pressure for new, and one and a half for old boilers; while both Hanover and Brunswick each have a somewhat similar regulation.†† The French law, and indeed most of the others, require two safety valves; and many are extremely minute in their directions with respect to glass gauges, steam gauges, and other fittings. In Great Britain there are no express legislative enactments with respect to boilers beyond those stated in two clauses of the Merchant Shipping Act, ‡‡ according to which (1) one safety-valve in every boiler of a vessel carrying passengers shall be placed beyond the

control of the engine-driver; and (2) any overloading of this valve is made punishable by a fine of not more than £100, "in addition to any other liabilities" which may be incurred by such an act. The boilers of all vessels carrying passengers, before clearing out of port, are subjected to a careful inspection by an engineer-surveyor of the Board of Trade, who can require the boiler to be tested in the usual way to twice the working pressure; and, if he think fit, he can, as the result of such an examination, place the option before the shipowner of either lowering the working pressure or renewing the boiler. Armed with such powers, the government surveyors are also responsible for any explosion which may directly occur through wear and tear. When an explosion takes place on a passenger railway, one of the Board of Trade inspectors of railways examines the fragments and reports upon the accident to the government board, who communicate it to the railway board. The reports are then printed, in order to be presented to Parliament, and this is the extent to which the British government can interfere in these cases. As with other railway accidents, however, the Board of Trade inspector is examined as a witness in any action for damages against the railway company. All other boilers in the United Kingdom are worked without any government or municipal interference whatsoever. Within late years, however, private companies (the first of which was organised by Mr. Fairbairn, of Manchester) have been formed for the prevention of boiler explosions. In return for a small annual fee, or for a small annual insurance premium, the boilers of any subscriber or insurer are periodically inspected, and, if required, tested by skilled engineers. There can be no doubt that these companies have already prevented a great amount of loss and disaster.

It may thus be said that there are three distinct plans for the general management of steam boilers:—1. There is the continental plan; 2. the free English and American mode; 3. what may be termed the Manchester system. The continental mode consists in a strict supervision, sometimes ruled by formulae, of the original construction, and there its action may be said, for the most part, to end. It does not, and cannot, without periodical inspections, take into account the effects of wear and tear. It may even be doubted whether the old French law, for instance, did not do more harm than good as regards construction. The official formula, according to which were calculated the thicknesses of the plates, founded as it was upon the assumptions that a cylindrical boiler formed an exact circle, and that a plate, however thick, conducted the same amount of heat to the water, was obviously incorrect. What may be termed the ordinary English and American plan throws the onus of proof of the negligence of the owner on those damaged by an explosion. This system is subject, besides other difficulties, to all the objections that exist against the trial of scientific questions by a jury, not composed of experts, and unaided by scientific witnesses. The continual occurrence of explosions in those cities and States of America in which boilers are used without any supervision by the authorities, and their undue occurrence in England with boilers that are not subjected to systematic inspection, sufficiently prove that steam boilers cannot be worked at hap-hazard. On the other hand, the system of organised inspection by the English boiler companies, and the similar system according to which the passenger vessels are inspected by government officers, have given universal satisfaction. A proper estimate of the value of the Manchester and Board of Trade system, compared with the continental and with the *laissez faire* plans could only be well based on numerous statistics. Unfortunately, such do not appear to have been formed. It is stated,* however, that in a average of 277 boilers, there were two explosions in the French department of the Haut-Rhin within ten years; and

* Bulletin de la Société Industrielle de Mulhouse, 1861, p. 525.

from 1856 to 1861, or within five years, there were only two explosions in an average of 1871 boilers, under the care of the Manchester Association. About four explosions occur annually amongst the 6,500 locomotives of the United Kingdom; three have already taken place this year. In an average of 600 passenger vessels inspected under the Steam Shipping Acts, only three explosions occurred since 1846-7 in Great Britain; viz: one at Lowestoff, in the *Tonning*; another at Southampton, in the *Parana*; and a third at Dublin. These last results speak very highly for the care and abilities of the Engineer Surveyors of the Marine Department; and the continental system is thus clearly inferior to that adopted by the Board of Trade. What is evidently wanted is that the system of skilled periodical inspection should spread over the kingdom. To a certain extent this is taking place, but this progress is slow, and needs some stimulus, while it is doubtful whether, in out of the way districts, the mere expense of inspection is not a great bar. What seems to be needed is that in the event of a fatal explosion the corner of the district should be enabled to write to the Home Office for scientific assistance in arriving at the originating cause. The Secretary of State might then call upon any competent engineer for a report on the matter, when he could be examined as a witness before the jury. The mere knowledge that any explosion would be strictly investigated by an expert, might, in many cases, be sufficient to counterbalance the too prevalent tendency to prefer risk to expense.

THE HYDRAULIC TEST.

Although, as we have seen, the application of a known amount of hydraulic pressure is in such general use for the determination of the strength of a boiler, there are, nevertheless, few points in engineering about the real value of which there is so much dispute. Everybody seems to have a different opinion on the matter. Some say that the hydraulic test is the only means of determining the strength of a boiler; others that it is a very injurious and useless measure. As to its amount, some recommend one-and-a-half, many twice, some thrice, and a few even four times, the working pressure. While numerous engineers advise its application to old boilers, others have strong objections to its use in this way. Whether the force-pump be really the best apparatus for its application, is, with other questions, also placed in doubt. The truth is that, while on the one hand, like other tests, it may be abused and wrongly applied, on the other its value may also be exaggerated.

The best practical proof of its necessity for new boilers is afforded by the fact that explosions have occurred the first time steam has been got up—such as that at the Atlas Works, Manchester, in 1858. Unless every plate be separately tested up to proof load, it is impossible to be certain whether one of them is not defective. This function is clearly much better performed by the hydraulic test. Then, as to its application to old boilers, much can be learnt during internal examination, but it is not always possible to tell the remaining thickness of the plates by this means, nor their deterioration through the heat. It is often said that a successful resistance to the hydraulic test is no proof that the boiler might not have been burst by a few pounds more; and that it may so suffer as to perhaps afterwards burst with a less pressure of steam. But this is no more true than it is true of a girder, for instance, which has withstood without permanent deflection its proof load. In every case it is necessary that its effects on the boiler should be exactly ascertained. In fact, the real test consists in this examination, and the proof pressure is only a means to this end. The boiler should, if possible, be subjected to a careful internal and external examination. With locomotives this can only be accomplished by taking out the tubes; with ordinary land boilers it can only be done by removing the brickwork. In fact, it may be said

that a steam boiler is never absolutely safe which cannot be easily examined—more especially from the inside. But by gauging the flue tubes, the combustion chambers, the flat surfaces, and even the barrels, it may be ascertained very nearly whether the limits of elasticity of the material have been exceeded—whether therefore the pressure has additionally injured a boiler which was near rupture already. It is often very plausibly observed that there is great danger in testing a boiler, which cannot be examined internally, to double, or even to only one and a half the working pressure. It is said that the test may strain the boiler without its showing any outward indication. It is certainly just possible that such a case might happen. A locomotive boiler, which had been tested with 196 lbs. pressure, the water being at 162° F., in September, 1860, but had not been examined internally, burst on the 1st of April, 1861,* under only 120 lbs. of steam. The boiler gave way at the smoke-box ring of the barrel, and, as usual, from a furrow or crack running close to and parallel with the inside overlap of the longitudinal joint. It is difficult to believe that if this ring, as well as the others, had been gauged after stripping the lagging from the outside, as is done by the engineers of the Manchester Boiler Association, it would not have shown a permanent increase of diameter or some bulging under the extra pressure. If, in addition to a neglect of careful measurements before and after the application of the pressure, this test is carried very high, then the whole operation may undoubtedly be a cause of that which it is intended to prevent. According to the Prussian law, every new locomotive boiler had to be re-tested to double the working pressure after running 8,000 Prussian miles, and afterwards for each 5,400 miles. These measures, while they did not entirely prevent explosions, greatly injured the boilers, by straining the staybolts, and by the resulting excessive caulking required to make the joints tight. On the other hand, the absolute security afforded by drawing the tubes can, under the present mode of construction, be only obtained at the expense of, perhaps, 300 tubes, costing from 26s. to 27s. each, besides some injury to the tube plates.

Whatever may be said against the hydraulic test, the best argument in its favour is its very general adoption. New Government boilers in the United States must be tried to a pressure two-thirds greater than the working pressure; the same measure being carried out with the 3,000 boilers in the city of New York. Mr. Anderson, C.E., of Woolwich,† directs his subordinates to use a test of at least double the working pressure for the boilers in the royal gun factories. Mr. Muntz, of Birmingham, has publicly stated that he has for years adopted an annual hydraulic test, "considering it a duty he owes to his workmen." The Eastern Counties, the South Eastern, the Lancashire and Yorkshire, the Caledonian, the North British, the Edinburgh and Glasgow, and the London and South Western Railway Companies employ the hydraulic test for both new and old boilers, using generally double the working pressure. The London and North Western are stated to have used it for only new boilers—at any rate, until recently. The Great Northern and the Great Western Railway Companies do not use it, and it is accordingly on these lines that the greater number of explosions take place. Practical experience thus proves that, though there is just a chance of the test failing to detect a weak boiler when it cannot be examined internally, the danger is greater in not using the hydraulic test at all. Mr. Beattie, of the London and South Western, strips the lagging every two years, and applies a pressure of 190 lbs., the working pressure being 125 lbs. Mr. Fletcher, of the Manchester Boiler Association, employs double the intended working pressure for new, and from $1\frac{1}{2}$ to $1\frac{3}{4}$ the working pressure with old boilers. The most commonly

* Board of Trade Report. 1861. Part 4.

† "Instructions to be Observed in the Management of Steam Boilers in the Royal Gun Factories."

used test is thus double the working pressure for old boilers, with a diminution according to circumstances as they get old.

An objectionable plan is measuring the pressure applied, and, for several reasons, one likely to lead into error, is estimating it from the load on the safety valve lever. A metallic gauge should be used, and very neat pocket instruments of the kind are sold in Paris. In frosty weather the rivet heads are liable to be snapped if the metal be not somewhat warmed by using hot water. The hydraulic ram kind of action on the sides is also much less likely to occur if a rather narrow force pipe be used for the pump.

There can be no doubt that it would be a valuable thing to be able to employ some means of measuring the permanent and the temporary extension of volume, if any, produced by the hydraulic test. It is probable that a boiler, as it gets old, and takes a permanent set under the pressure, also increases in volume; so that it doubtless holds a few gallons more than it did when new. An ingenious plan for measuring the increase of volume is recommended in the Bavarian regulation. After the boiler is filled, the amount of water forced in is measured by pumping it from a vessel marked with divisions. When the pressure is removed the boiler contracts more or less, forcing out at least a portion of the water; the amount remaining is supposed to give the dilatation of volume of the boiler. The difficulty in the use of this plan would probably consist in the presence of air in the water itself, and any which might chance to remain in the boiler. That in the water might be greatly diminished, or at any rate brought down to a constant amount, by boiling; but there would be no precise security against any air in the boiler, and as the weight of the air absorbed by water (according to a well-known law) is in proportion to the pressure, it would be taken up by the water, thus falsifying the indications when the pressure was removed. On the other hand, a high temperature of the water would form an impediment to this absorption. The experiment is certainly worth trying. It might be very valuable with tubular boilers inaccessible from the inside, as any permanent set or deflection ought to be indicated by little or no water being compressed out by the contraction of the boiler on the removal of the pressure. As long ago as 1844, M. Jobard, of Brussels, in order to obviate the supposed injurious effects of the hydraulic blow of the water on the plates, proposed to fill the boiler with water, first loading the safety valves, and to then dilate the water, and consequently the boiler, by means of heat applied to the outside.* More recently, Dr. Joule, of Manchester, has used the same plan himself, proposing it for general adoption.† In addition to the loaded safety valve, he used a metallic pressure gauge "to be constantly observed, and if the pressure arising from the expansion of the water goes on increasing continuously without sudden decrease or stoppage until the testing pressure is obtained, it may be inferred that the boiler has sustained it without having suffered strain." Another plan, also founded upon the same principle of the irregularities of extension of metals when the limit of elasticity is exceeded, has lately been proposed.‡ This consists in bringing an ordinary steam-engine indicator in communication with the pump plunger as if it were a steam-engine piston-rod. The ordinates of the pencil diagram would thus give the pressure in the boiler, while the respective abscissæ would give the quantity of water pumped in at each stroke. As long as the limit of elasticity was not exceeded there would be a horizontal line, while a curved line would appear as soon as the sides began to take a permanent deflection. There seems

to be a sort of contradiction in depending for results like these upon such irregular appearances as the extensions beyond the elastic limit. But all these proposals are undoubtedly worth trial in practice. Dr. Joule's plan has the merit of affecting the plates by both heat and pressure—thus bringing them under every-day conditions.

DISCUSSION.

Mr. LEWIS OLRIK said there were some points in the paper with which he did not agree. It was stated by Mr. Paget that one cause of injury to steam boilers was the percussive action of the steam when suddenly cut off by the slide valve, which caused a recoil upon the sides of the boiler. On this point he would remark that, in the great majority of boilers used in England, the slide valve did not suddenly cut off the steam; in most cases the slide valve was moved by an eccentric, and the cutting off was gradual, and not sudden, as in the case of the American engines; and this remark, therefore, only applied to those engines where the expansion gear acted suddenly. Allusion had been made to the straining of the cylinder covers. He had seen such cases, and he had also observed the foundation-plate give at each stroke of the engine; but he had no doubt, if Mr. Paget had examined the plates in such cases, he would have found that this was not caused by the percussive action of the steam, but was owing to an insufficient amount of metal and insufficient strength put into the proper place. He had noticed this in the case of an engine of 20 horse-power, which had been in use for many years in the factory of Messrs. Maudslay, where there was an insufficiency of metal in the proper place. He had never seen it where the cylinder covers were strong enough for the work they were expected to do. Another point mentioned by Mr. Paget was, that the steam room in the boiler should be proportionate to the size of the cylinder; he should have been glad if Mr. Paget had stated what he considered to be the proper proportions. Reference had been made to the caulking of boilers under pressure. This might be done when a boiler was tried by the hydraulic test, but the proper way was to take off the pressure, and then caulk and put on the pressure again. It was only the question of a minute to pump the pressure up again, and a few strokes more gave the additional pressure, beyond the former one indicated by the chalk mark. The next point he would allude to was with regard to the feed water. It would appear that many engineers did not consider it wrong to insert the feed water pipe near the fire box. Quite recently he had seen that done in the case of a locomotive, in which a Giffard's injector was employed; and he would call the attention of those who had not considered the subject to the explanations which Mr. Paget had given as to the injurious action of the feed water on the boiler plates. The next point in the paper had reference to the superior heat-conducting power of thin boiler plates as compared with thick. This was no doubt the case, but in speaking of the American plates, Mr. Paget had omitted to mention the superior quality of those plates, which made it possible to use them of a thickness which would not be ventured upon in England. Within the last few years the quality of the best plates in this country had almost come up to the American standard, but those generally used were not so good. Allusion had been made to the voltaic action that took place in steam boilers, and the evils that might follow from it. Some years ago a pamphlet was published by Mr. Zerah Colburn, in which the action of steam-boiler explosions was explained, and the question of the galvanic action was based upon the high authority of Professor Faraday, to which he (Mr. Olrik) would willingly bow. He entirely agreed with the general remarks in the paper with respect to explosions. They involved the sacrifice of a great amount of life and property, and he thought it would be desirable for the Government to take this matter in hand, and to in-

* "Technologist," 1844. p. 135.

introduce stringent rules to make people more careful with their boilers. The greatest amount of mischief was occasioned by employing men to attend to boilers who knew nothing whatever of the properties of the steam-engine. It was a question which could not be too much impressed upon people, that there should be proper periodical inspections of boilers, according to the system adopted by the Manchester Association. Mr. Paget had mentioned the hydraulic test. There was a great difference of opinion amongst engineers on that question, but no doubt, as Mr. Paget had pointed out, practical experience led to the conclusion that in all cases where this test was carefully applied there were much fewer explosions than where it was neglected. The cases of locomotive engine explosions had occurred solely on lines where that test was not employed. On the subject of the wear and tear of steam boilers he would remark that the great cause was defined by the single word "neglect," often on the part of the designer and manufacturer. When a boiler was made too small there must be forced firing, and the consequence of that was early destruction of the boiler. A further deteriorating cause was defective circulation, producing similar consequences. There was one point which it was almost unnecessary to mention, viz., that if boilers were not properly stayed they would give way earlier than if proper attention was paid to the staying. But the great evil arose after the boilers came into the hands of the owners, from employing unskilled persons to work them. The amount saved in wages in this respect was an injudicious economy, and it was a question whether parties who confided boilers to such people ought not to be made responsible in a court of justice in the event of explosions taking place. Amongst the various evils to which steam boilers were exposed there was none worse than bad feed water, which was a frequent cause of their destruction. A most grievous evil was scale in the boiler, which lowered the heating power, and thus it was most important that it should be frequently removed. Scaling arose from bad water, but as rain water was not generally to be procured, they had to be satisfied with well water, which was generally very hard, and which led to large deposits of sulphate of lime in the boiler. For the removal of the carbonate of lime from the feed water, he believed Dr. Clark's process was very effective, though the means by which the result was accomplished would appear strange to those unacquainted with the subject. Lime was added in excess, which caused the precipitation of the salts of lime already in solution, and thus the water was purified.* There was also another plan, which had been successful in preventing scale, known as Martin's invention, which he had no doubt was also efficient. In that plan the feed water was made to pass through a cylinder containing plates arranged diagonally and filled with superheated steam; the water deposited its scale upon these plates before entering the boiler. The consequence of this was a clean boiler instead of the accumulation of scale. The usual way of removing scale was sending boys with hammers into the boilers and knocking it off, which often caused great injury to the structure of the boiler, from carelessness in the operation. He was sure they must all feel indebted to Mr. Paget for his valuable and exhaustive paper.

Mr. STENSON remarked that mention was made in the paper of the circumstance of the stay bars in boilers being in a crystalline state, and only requiring a slight blow of a hammer to break them. He had heard papers read before this and other societies in which this question had been debated, but there was one point which required first to be settled—viz., the real condition of the iron previous to its being made into stays. Was it crystalline before it was so used? or had it become so by use? He had been connected with engineering the greater part of his life, and he must say he had never met with

an instance in which it was satisfactorily proved that the iron had been converted from its fibrous condition before use. It was asserted that percussive action tended to produce a crystalline condition of the iron. This might be so, but he required further proof of it. He had cut up and examined a great many piston-rods and connecting-rods of locomotive engines working at great velocity; he had found them to be in various states—some partly crystalline and some entirely so, while others had remained fibrous throughout; and he had found the same characteristics of inequality in the tires of railway wheels. The leakage of boilers had been referred to in the paper, and he held it to be a very important subject for investigation. He knew, from experience with boilers in his own use, that a very small leakage would destroy the plate from the outside. The oxydation commenced at the spot, not where the water leaked, but where it evaporated and the plate was dry. The destruction of the plate from this cause was so rapid that he had known a $\frac{3}{8}$ -inch plate cut through by a small leakage in a few months after the boiler was put up. He had no doubt this was caused by the chemical action of the water upon the plate. With regard to scale, Mr. Olrick had mentioned a plan which he regarded as efficient in preventing the usual effects of the deposition of carbonate and other salts of lime in steam boilers. There could be no doubt of the destructive effects of those deposits upon the plates of the boiler, as also of the retardation thus caused to the heat. He should be glad to hear some further explanation of Mr. Martin's process, as he regarded scale as the greatest element of destruction with which they had to contend in the working of steam boilers.

Mr. ADAMS, whilst agreeing to a great extent with what had been stated in the paper, took exception to the remark that the method of welding plates reduced their strength. He had seen many successful experiments in welding, by Bertram's process, at Woolwich, and it was invariably found, under ordinary circumstances, that the weld was the strongest part of the plate, for it was a well-known fact that a piece of iron forged after it came from the rollers was stronger than when it left the rollers. Mr. Paget had quoted from some German authorities respecting the temperature at which water was decomposed, but he would state a practical fact within his own experience. On one occasion the steam was allowed to stand stagnant in a superheater for ten days, and on the tenth day the metal of the superheater ran away into the fire, but no decomposition of the water had taken place. With regard to the hydraulic testing of boilers, engineers were not agreed as to whether the testing should be made at a high temperature or not. They knew, in testing a boiler cold, they had the friction of the rivets; but in hot testing the expansion of the metal by heat caused a great difference. The rivets expanded to a greater extent than the plate itself, because the expansion of the rivets was longitudinal and along the fibre, whereas the expansion of the plate was across the fibre and not so great, and the power which the friction of the rivets gave to the strength of the plate would be less when cold; but to oppose that there was the greater strength of the plate due to the low temperature. Mr. Adams then, by means of a diagram, described in detail Martin's process for preventing incrustation in boilers.

Mr. G. F. WILSON, F.R.S., on the subject mentioned in the paper as to water or steam in contact with iron being decomposed, would give an instance in his own experience where such was not the case at a very high temperature. It had come under his observation that steam passing day by day through iron pipes at a red heat was not decomposed, or there was no evidence of its decomposition. The theory was that hydrogen ought to have been formed and an explosive mixture should have been generated, but practically such explosive compound was not formed.

Mr. OLRIK wished to add, with reference to the hydraulic testing of boilers, that he had in many in-

* *Journal of the Society of Arts*, vol. iv., p. 424.

stances used hot water for the test up to 200 degrees, as by that means the boiler was brought into a very similar state to what it would be in when at full work.

The CHAIRMAN said it now became his duty to move that the thanks of the meeting be given to Mr. Paget for the paper with which he had favoured them. It was very comprehensive in its scope, and he thought contained many valuable suggestions. No doubt public safety was of the first importance in matters of this kind, and the mode in which that could be best obtained seemed to be practically indicated by the inspections undertaken by the Manchester Society. Other means no doubt might be taken for ensuring the safety of the public; but there was no plan so effective as when the public took care of itself, as was the case at Manchester. With regard to the economy of wear and tear, it was a question for engineers, and one upon which he could not venture to give an opinion; but, undoubtedly, it was an important question for those who employed steam boilers in their manufacturing in which a large amount of capital was invested. They must all feel indebted to Mr. Paget for his careful investigation of the subject, and the able manner in which he had treated it in his paper.

The vote of thanks having been passed,

Mr. PAGET, in acknowledging the compliment, said that a perusal of his paper would show that he had very carefully guarded himself from stating that any impulsive action on the sides of the boiler could be brought to bear by means of the gradual action of the side-valve. In speaking of the effect of galvanism on steam boilers, he of course only meant the chemical action on the plates producing wear and tear, and therefore the primary ruptures leading to explosions. With respect to incrustations, he thought that the effects they produced were simply those which ensued whenever a plate got red hot. In speaking of the charcoal plates used in America, he was necessarily aware of their superiority to iron made with pit-coal. Testing boilers by means of hot water instead of cold, was often, as he stated, very advantageous, and, indeed, necessary. With regard to the crystallization of iron, and with respect to Mr. Stenson's remarks, he thought that this state was simply due to strains in excess of the elastic limit, abstracting elasticity and ductility, and therefore inducing brittleness. The crystallized appearance of a surface of fracture was simply due to the mode of fracture. His observations with regard to Bertram's joints were founded on the results of experiments conducted at Woolwich for the Admiralty. With respect to boiler insurance companies, their action undoubtedly offered the best means of safety and economy; at the same time, their future spread needed some extraneous stimulus, more especially in sparsely populated districts, like the agricultural and some of the mining counties.

DUBLIN INTERNATIONAL EXHIBITION.

The Natal Court attracted great attraction at the Exhibition in 1862, from its wild and picturesque objects of native industry and sports of the chase, and it will be equally well represented at Dublin this year. From an interesting local account, the following particulars are taken:—

First comes the interesting collection so opportunely contributed by Mr. Barry. That gentleman has recently returned from his long and devious trip across the continent, and some of the curiosities which he has gathered together during his journeyings are new and rare. These articles are very illustrative of domestic life among the Bechuana tribes of the interior, and especially so of the people living around Lake Ngami. We doubt whether such a gigantic pair of bullock horns has ever been submitted to British eyes as that presented to Mr. Barry by Lechulatabe, Chief of the Batoana. They are certainly second only to the monster pair in the first Inter-

national Exhibition. Several pairs of rare buckhorns are also contributed by Mr. Gifford, Mr. Baker, and Mr. Topham. The gemsbok horns, lent by the first of these gentlemen, are, from their size, very interesting. To the same class belong the skins of various antelopes and animals. The poisoned arrows belonged to Bushmen, and are made of dwarf reeds pointed with bone spines, thickly covered with the deadly poison obtained from a small beetle which infests a tree of the mimosa tribe. The arrows are found in the same sheath as the arrows are the roughest mode of ignition known. The upper stick has to be twisted in its charred socket for about ten minutes, before the sparks are created. Some caps and head-dresses, made of feathers and skins and worn by the Bechuana near the Great Lake, show how the barbaric ideas of costume advance as we go northward. They are principally worn on frosty nights—for in the winter months of the mid-year the cold around the marshy borders of the lake is severe. Among other domestic accessories picked up by Mr. Barry are some rattles, made of large seed pods; a fan, formed from the tails of golden jackals, and which are also used for the purposes to which pocket-handkerchiefs are generally applied; some spoons and ladles, cunningly carved in twisted shapes, from solid pieces of wood. There are also some articles in this part of the collection valuable in a commercial sense. The fibres are very fully represented, both in their raw state and in various kinds of twine, cord, and thick rope, made and used by the natives round the Botlletle river. These fibres are mostly obtained from different varieties of marsh grass, and the rope exhibited has been employed in the trapping of elephants and the capture of hippopotami. A hundred yards of very strong fishing netting, as used in the waters of Ngami, show how large and valuable are the fibre resources of all Southern Africa. The tribe from which these specimens were got is the Bajeye or Bakoba. Reference should be made to the large earthenware jar, which, as superior specimens of native pottery, well deserve inspection. In this lot will be found a war knife, with an oddly-carved shaft. This comes from a tribe living to the south of the Zambesi, and never yet visited by a white man. Perhaps the most grotesque object is the rudely carved elephant, a primitive specimen of sculpture. These are the principal items in Mr. Barry's contribution, which is likely to be the best assortment of African curiosities in the Exhibition.

There are, however, other more local representatives of native industry. Mr. Topham's valuable collection comprises the entire range of Zulu Kafir economy. The hard, grim looking logs of stained wood are the pillow and stools which form almost the only furniture in the native's hive-like hut. The little snuff-spoons, with their long prongs for insertion into the woolly wig adorning the manly brows of the savage, are no mere ornament, but, in consort with the snuff-boxes, made out of small gourds and calabashes, are in constant use every hour of the day. Nor is the office of the stone pipe a sinecure. This perhaps represents the most primitive form of narghileh. Seated in a circle, this calumet is passed from hand to hand, until the enchanted smokers subside into a watchful stupor, caused by the strong fumes of the *dacca* or native hemp, whose smoke is inhaled through the water at the bottom of the cow-horn. Some idea of native aptitudes for mat-making and basket-work will be gathered from the specimens shown. That the natives are not devoid of the artistic faculty, a glance at some pieces of bead-work will show. Since it became compulsory on natives to enter the limits of townships clothed, the demand for beads has not been so great. Fashions regarding them vary very much. Sometimes large red ones will be in vogue, at other times small speckled ones. It is at their kraals, however, on state wedding occasions, that the Zulus may be seen to the greatest advantage in their panoply of beads, feathers, skins, and other savage finery. There is also a bundle of *Amazosa assegais*, and a very interesting Bushman spade, sent by Col. Maclean. The

ormer are as suggestive in their way as the spears displayed in the Tower, while the last, it must be remembered, is the industrial handiwork of a race which ranks lowest in the scale of humanity. Perhaps, however, the most remarkable of all these native curiosities is the gigantic and very striking piece of wood-carving exhibited by Mr. Horwood, and obtained by him from the native who made it in Zululand. This strange object consists of three graduated central bowls of carved wood, stained black, and diminishing in size as they rise upward. All around them smaller bowls project, and each has its basin-like cap. The height of the whole structure, —for it really deserves that name— is nearly five feet, and its diameter about three feet. It is entirely hewn and cut from one solid block of wood, and it took the maker, who had only a knife to work with, eighteen months to execute. Its use is to hold beer. Old African travellers say that they have never seen anything at all equal to this extraordinary production.

The most valuable part of the collection is that which illustrates the industrial and commercial resources of the colony itself. But allowance must be made for the hurried nature of the effort. The articles that are exhibited have been hastily got together, and they must by no means be taken as a pattern sample of what Natal can grow. In regard to sugar, which may be looked upon as the staple product, there is a sample of the best yet made in Natal by the ordinary process. It comes from the estate of Mr. H. Shire, on the Umhlanga, and was made in his battery by Mr. Collard, a Mauritian sugar-boiler of great experience. In size and purity of grain, it almost equals sugar made by the vacuum pan process. The vacuum pan sugars from Canonby estate are *sui generis*. No other plantation yet possesses this important appliance. Altogether the array of sugars will be enough to prove that Natal is equal, as a sugar-producing country, to either the Mauritius or the West Indies. Mr. A. Wilkinson's display of rum, rectified spirits, and rum shrub will be a new feature never exhibited before. The spirit is manufactured from the refuse of cane crops, and is fit for chemical purposes or varnish.

Mr. Baker shows samples of wool and angora hair well prepared, and there are also fine samples clipped from the flocks of Mr. Mesham and Mr. Tomline.

The Cotton Company's bales of cotton are better samples than those shown in 1862. Mr. T. Reynolds sends a beautiful parcel of cotton from Oaklands. Mr. Martin's hank of wild cotton twist, from near Delagoa Bay, and the sheet made therefrom, may afford some speculation to those interested in the discovery of new fibres. The very fine samples of flax from Messrs. C. Hunter and Co.'s flax-works ought to attract some notice in Ireland, where this staple gives support to so many people. Mr. Benningfield's aloë and pineapple fibres show to what purpose two plants—one of which is met with wild while the other grows like a weed—can be put. In Mexico, the Indians and the half-castes dress largely in fabrics made of the agave. There are hosts of fibres little known to the scientific or industrial world, but very valuable withal, existing in a wild state in this colony and the interior. Dr. Mann's collection of woods is complete so far as it goes, though necessarily not so numerous as in 1862. Mr. Topham also sends some beautifully prepared woods, many of which take a fine polish. No better-flavoured tobacco can be desired than that of Mr. C. Manning. Rich, mild, and fragrant, it is just what a critical smoker would desire. Mr. Hodgkin also sends colonial cigars. Cayenne pepper is abundantly represented from samples from Mr. P. Steel, Mr. J. P. Voysey, and Mr. Russell. All, however, differ in colour and quality. There need be no limit to the local production of this article—the pulverised capsule borne by the chili and capsicum bushes. Arrowroot is only represented by a sample from Mr. Stainbank, the last season's supply having been all shipped.

Corn is not so fully or fairly represented as could be

wished. Messrs. Henderson and Scott's wheat proves however what can be done in that way, and Mr. Baker's oats are equally as significant; but of the great item of maize—the staple corn stuff of the country—there is only one sample. Mr. Topham has also sent a piece of copper, mined and smelted by the natives. Coals have not been overlooked, Mr. Baker having forwarded a box of superior specimens. These will go to show that the Coal Company has something tangible to support its designation. The local smiths never hesitate in giving the preference to colonial over imported coal—the former burns so long, so bright, and so well.

Mr. P. B. Short has contributed luscious and tempting conserves of pine-apple, bananas, and amatungulu. The last-named, being a native fruit, will be new to those who look at it. The syrups made from the same fruit, and from the pineapples, have golden and delicate pink tints that are very pleasant to the eye. The copies of Messrs. Davis and Son's Naval Almanacs are a creditable example of our literary and typographical capabilities; and the maps sent by Dr. Mann will assist the spectator to form an intelligent comprehension of the colony from which these articles have come. Messrs. Brock have promised some of their excellent photographs; but Dr. Mann's photographs of Bishop Colenso's "intelligent Zulu" and his wife, will excite as much interest as any other item on the list.

THE PARIS EXHIBITION OF 1867.

The Belgian Minister of the Interior has addressed the following circular to the governors of the various provinces:—

"M. LE GOUVERNEUR,—A Universal Exhibition of the products of agriculture and industry and the fine arts is to open at Paris on the 1st of May, 1867. A Commission, presided over by his Imperial Highness Prince Napoleon, has been charged with its preparation and direction. By request of the French Government, a committee has been now instituted in Belgium to place itself in communication with the Imperial Commission, in order to furnish it with the information it may require respecting our country, and bring before it the wishes of our manufacturers.

"This committee consists of M. Fortamps, Senator, formerly Chairman of the Belgian Committee at the London Universal Exhibition, President; M. Adam, Director-General of Direct Contributions, Customs, and Excise; M. Bellefroid, Director-General of Agriculture and Industry; M. Romberg, Honorary Director-General of Fine Arts; M. Moxhet, Director of the Consulates; M. Kindt, Inspector of Industry, Members; MM. Dulieu and Clerfeyt, Secretaries.

"The committee is authorised to place itself directly in connection with you, as well as with the Chambers of Commerce, Commissions of Agriculture, and other competent bodies, for everything concerning the mission with which it is charged.

"Be kind enough, M. le Gouverneur, to give the committee the assistance it requires to accomplish its task, and to allow it to find the same willing aid among the authorities to which it may have to address itself.

"Everything appears to indicate that the Universal Exhibition of 1867 will have an exceptional importance and brilliancy. The development recent Customs reforms have given to the commercial relations of France and Belgium, already previously considerable, and the extension these relations may still receive for the advantage of the two countries, permit us to suppose that our producers will endeavour to occupy a distinguished place, worthy of their renown, and conformable to their interests.

"In any case, as it is important that we should have a sufficient notion of the amount of space which should be reserved for the products of our fellow-subjects in the Exhibition building it is intended to construct, I request that you will take what you consider the most efficient

means of ascertaining the requirements of those persons in your province principally interested in the Exhibition of 1867. If you cannot yet obtain precise information as to the exact space our exhibitors will require, you will at any rate be able to procure general indications as to their probable participation in the coming Exhibition, and thus to furnish me with those elements without which the interests of our countrymen might not be sufficiently guaranteed.

"I request you, M. le Gouverneur, to omit no pains to obtain the most exact information, and to place yourself for that purpose directly in communication with the competent authorities and the chief manufacturers of your province. I ask your zealous assistance in this matter, and, as the affair is urgent, pray you to acquaint me with the result of your inquiries with the least possible delay.

(Signed) "A. VANDENPEEREBOOM,
Minister of the Interior."

Fine Arts.

PARIS EXHIBITION.—The annual exhibition of Fine Arts opens, as usual, in the Palais de l'Industrie, in the Champs Elysées, on Monday, the 1st of May, and the collection is expected to be beyond the average in quality, as it will certainly be in quantity. The weather just now is magnificent, and those who can spare the time for a trip to Paris in May, or the first half of June, will have a fair chance of seeing the city in its gayest aspect, besides having the opportunity of studying the results of French art on a large scale, and at their ease, for the size of the building and the enclosed garden, in which the sculpture is always admirably exhibited in the midst of green lawn and glowing flowers, supply together one of the finest places for such a purpose in Europe.

PHOTOGRAPH OF DANTE.—The portrait of Dante painted by Giotto in a fresco in the chapel of the prison of the Bargello, in which the immortal poet was once incarcerated, is well known to the artistic world, but the engravings of the work give but a very poor idea of it. A photographer has recently succeeded in obtaining an admirable reproduction of it, which is about to be published in five different sizes, from that of a *carte de visite* to half that of the original.

Manufactures.

TUSCANY STRAW WORK.—It appears by an official report that the annual value of this industry is about half a million sterling. The soil of Tuscany is said to be the only kind in Italy which will produce straw of sufficient fineness for the purpose, and it is only in the immediate neighbourhood of Florence itself that the highest quality can be produced. The farmers of the Romagna, the Marches, and of Naples, have often attempted to grow it, but have never completely succeeded. The straw in question is that of a peculiar kind of wheat, which never attains more than fourteen or fifteen inches in height, and bears very few grains of corn. The sewing together of the plats is as nice an operation as the plating itself, and each requires great practice and infinite patience. More than half a million of straw bonnets are made each year in Florence. In certain localities, such, for instance, as Empoli, 4,000 or more women are employed in the trade; Sesto has about half that number.

GALVANIC PILE.—At a recent meeting of the Academy of Sciences, M. Matteucci read a paper "On the Action of Sulphur in the Galvanic Pile." The author has experimented on the battery recently introduced by M. Blanc, who employs a plate of zinc and a plate of lead covered with a very thin deposit of copper, which are placed in a solution of common salt, with which is mixed a quantity of sulphur. This battery appears to be very useful for

telegraphic purposes, and the only objection to its use is the evolution of some sulphuretted hydrogen, which would seem to be unavoidable. In the course of his experiments the author arrived at the following conclusions:—1. That finely-divided sulphur in contact with the electro-negative metal of a pile formed of zinc, copper, and solution of common salt notably increased the electric motive force, constancy, and permanency of the battery, and he hopes to obtain by the use of sulphur a voltaic combination possessing many advantages over the battery at present employed. 2. Sulphur, although insoluble and an insulator, enters into combination with the sodium set free by the current. It remains for the author to explain the action of the small quantity of sulphide of copper which is formed, and which appears to be essential. For this end he has undertaken further experiments.

Commerce.

THE STAGNATION OF COMMERCE.—Messrs. Tassell and Son, in their circular, say:—"Probably at no previous period has there ever been a more general stagnation of commerce than at the present moment. Instances have been known of more severe depression in this and other countries, but none in which the limitation of business was so universally observed in all parts of the world. In the United States the imports of the past six months have scarcely been more than a fifth of those of the corresponding months of last year; in India the suspension of transactions is reported by the most recent telegrams to be almost complete. From China the accounts are equally discouraging, while in South America, Australia, &c., although the markets are less flat than elsewhere, there is no particular activity. Of course the brunt of this great change will have to be sustained by England; but our manufacturing and producing power is so extensive and varied that we have more capability than other nations of sustaining ourselves under exceptional circumstances. Hence, although the evidences of the contraction of trade are seen among us on all sides, they are less apparent here than in France, where the unprecedented rapid accumulation of the stock of bullion is a consequence of the reduced demand for money for commercial purposes. At the beginning of the year it was a question in this country, whether the diminution in the commercial demand for money, would so far counteract the effects of the requirements for our headlong commitments to foreign loans and undertakings, as to allow a decline of the rate of discount to 5 per cent.; but it is plain that the extent of the impending revulsion was then underestimated, and now that the slackness in our industry has been aggravated by circumstances taking place in the iron trade, which have caused large orders to be sent to Belgium, the prospects seems to be that the rate may remain for some time at the present point, even if it should not temporarily go below it."

Colonies.

COLONIAL SOCIETIES.—A movement has been originated in Victoria for the establishment of a Society of Arts, Manufactures and Commerce, the objects of which are to be the encouragement of arts and manufactures in this colony by disseminating information thereon, and by bestowing pecuniary and honorary rewards for such productions, inventions, and improvements in this department, and the introduction of new industries, as tend to promote emulation, economy, and consumption, more extended employment, increase of social enjoyments, of trade and commerce, and of national wealth. A similar society is suggested in the Hobarton papers for the colony of Tasmania, which has already done much good through its Royal Society, Mechanics' Institutes, Agricultural and Horticultural Societies.

ACCLIMATISATION IN VICTORIA.—At a meeting of the Council of the Acclimatisation Society of this colony, a letter was read from J. A. Youl, declining to undertake the shipment of another lot of salmon ova, and stating that he has for various reasons been obliged to decline a similar request made by the Tasmanian salmon commissioners. A letter was read from Mr. R. Philpott, giving some further particulars about the shipment of Angora goats, and advising that, if possible, a further sum of money should be sent home for the purchase of these animals. Dr. Black mentioned that it was at his suggestion the Council had determined to import some of the Angora goats, convinced as he was that there was no animal more worthy of the exertions of the society, or one that would redound more to their credit to establish there. After a conversation as to what amount should be set apart for this purpose, it was unanimously determined to devote a further sum of £900 for the introduction of Angora goats, thus doubling the amount already in Mr. Philpott's hands. A letter was read from Mr. Layard, of Colombo, stating that he had sent three axis deer and one Ceylon elk. (These have arrived in good condition.) Letters were also read from California, stating that seven of the Californian mountain quail had been received at the Botanical Gardens, and that the Sambur deer had arrived safely at Yallock; and speaking in sanguine terms of these fine animals soon penetrating into the Streletsaki Ranges, and becoming established there. The secretary reported that he had received two tortoises and two ostrich eggs from Mr. J. Mackie, who brought them from the Cape. Mr. Mackie states that it is now quite a common thing for the farmers to have a flock of ostriches in a state of semi-captivity, and that a very large profit is derived by the sale of the feathers. Mr. Mackie thinks that the eggs might without much difficulty be brought to this country and hatched, where he has no doubt the breeds would thrive and do well. They were to be collected together at the Exhibition building between the 1st and 10th of March, and the whole despatched by the *Great Britain*, which was to sail on the 15th of that month. The board appointed to promote the objects of the present undertaking have availed themselves of the experience of Mr. J. G. Knight, the secretary to the commissioners for this colony at the London Exhibition in 1862, in the executive management of the matter.

Notes.

DANISH INDUSTRIAL EXHIBITION.—The Danish papers contain intelligence that the Government has resolved to hold an industrial and artistic exhibition at Copenhagen in 1866. A committee has been formed for the purpose, consisting of twenty-five members, presided over by the Crown Prince Frederick. The chairman of the committee is Councillor Forchhammer. The exhibition is to be opened on the 1st June, 1866, in the riding-house of the Castle of Christianborg, and will include raw stuffs, as well as manufactured goods and objects of art.

HYDRAULIC WORKS IN THE DOUBS.—A very important work is about to be undertaken in the department of the Doubs, in France, with the object of economising and regulating the waters of the lakes of Saint Point and Remoray, and of improving the river Doubs from the lake of Saint Point to the point where the Doubs empties itself into the *Sône*. The actual level of the lakes is to be lowered, two hundred acres of marshy land reclaimed, and the drainage of the entire neighbourhood re-arranged; finally the lakes will be deepened, so as to increase and regulate the water power, which is used by ninety factories of various kinds on the Doubs. The cost is estimated at £96,000, but the value to the existing factories is set down at £24,000, and it is expected that a large number of new works will spring up in consequence of the improvements to be made.

AUTOGRAPHIC TELEGRAPH.—It is officially announced that the new telegraph, which heretofore only operated between Paris and Lyons, will be opened to the public, on the 1st of May, between the former city and Havre.

GAS LIGHTING IN PARIS.—The consumption of gas in Paris has doubled in the eight years from 1857 to 1864. The *Compagnie Parisienne d'Eclairage* sold, in 1857, 1,979,134,379 cubic feet, and in 1864, 3,870,600,105 cubic feet, about half the total quantity supplied. There are about 687 miles of mains only. There is a good market for the coke, and the ammoniacal sold for £5,121. The Paris Company, in order to induce the sale of their coke, make and sell at cost price a stove specially adapted for burning this material in houses and shops, and of these stoves they sold no less than 2,755 in the year 1864; the total number in use at the end of that year was 11,291.

LENOIR GAS ENGINE.—There were, on the 31st of last December, no less than 143 of these ingenious, simple, and compact little engines working in Paris to the satisfaction of those who employ them.

Correspondence.

CITY HORTICULTURE.—SIR,—As city horticulture is by no means confined to flower shows, so neither is window gardening restricted to pots of flowers, or to appliances to be added after the houses are built. If window gardening be a pleasant and cheerful thing why should it not be provided for in the first instance by architects in their designs, and by builders in their structures? By the provision for the indulgence of this taste thus becoming a forethought instead of an afterthought, not only would greater capacity be obtained in the receptacles for these miniature *parterres*, but greater elegance and more harmony with the elevations of the buildings. Indeed, it may fairly be hoped that improved arrangements for the gratification of this taste may lead to new architectural features of much beauty. For instance, the sills of windows are sometimes made to continue the string courses running along the frontage; that is, often the string courses run immediately below the windows. If, therefore, the receptacles of these miniature gardens project somewhat, immediately at the base of the windows, and they are ornamented with patterns, why should not these patterns be continued on the string course? If these receptacles be in iron, they might be painted terra cotta colour and the rest of the string course be supplied in terra cotta to match, or if porcelain or encaustic tiles face the window gardens, why may these not also be continued in the same fashion on the remainder of the string course? Supposing two or three rows of windows on a house or row of houses thus decorated with different agreeable patterns running along the string courses and window-gardens, they would surely have a pleasing effect? If a builder, in constructing a row of houses, say, for the artisan class, were thus to fit up and decorate each alternate house with window-gardens, leaving each alternate one plain, I fancy he would find that the former would go off his hands before the others. And I would submit the suggestion that a premium for such designs of house elevations, combining window gardens in pleasing harmony with architecture, might legitimately appear in the Society's prize list for next year. We frequently hear complaints of want of novelty in architecture, and provision as above for the indulgence of the taste for flower-growing, in union with architecture, in this most nature-loving metropolis, would afford one feature of originality which would really belong to us.—I am, &c., JOHN BELL.

PHOTOGRAPHY ON PAINTING CANVAS.—SIR,—Will you kindly correct an error which occurs in your journal of the 21st inst. On page 380 credit is given to the Belgians for having devised a successful method of printing by means of photography on painters' canvas. The method referred to is my process with collodio-chloride of silver, described at a recent meeting of the Photographic

Society. I described its application to painters' canvas in the *Photographic News*, on February 10th. The article in which I described it was translated into a Belgian journal, and duly acknowledged; from thence it was transferred into a French journal, quoted as from the Belgian journal, the acknowledgment of the original source, doubtless inadvertently, being omitted. This is probably the origin of the error. By correcting it you will much oblige, yours, &c., G. WHARTON SIMPSON.

Patents.

From Commissioners of Patents Journal, April 21st.

GRANTS OF PROVISIONAL PROTECTION.

- Air engine (compressed)—818—A. B. Baron Von Rathen.
Alumina, sulphate of—900—A. A. Croil.
Boots and shoes, feet protectors to be used loose in—908—J. Poole and T. Brown.
Buildings, construction of—822—J. Tall.
Buttons—1007—G. Davies.
Cartridge boxes—902—A. V. Newton.
Centrifugal force, rinsing and drying by—804—H. A. Bonneville.
Coal, machinery for mining—558—G. Lander.
Coffee, substitute for—979—M. Droy.
Cornice rings, manufacture of—977—C. H. Williams.
Corners, ventilation by perforated tubular—813—T. H. Saunders.
Drying wool, cotton, &c., system of—255—E. T. Hughes.
Engines, governors or regulators for—991—S. Smith & J. W. Jackson.
Engines, traction—962—J. G. N. Alleyne.
Fabrics, dyeing and printing—804—A. Paraf.
Fibrous substances, machinery for carding—983—J. Ellis, C. Walker, and W. Preston.
Fibrous substances, preparation of—948—A. and H. Illingworth.
Files, machinery for cutting—1013—T. Turton.
Fire, apparatus for giving alarm in case of—267—M. Cartwright.
Fire-arms—969—C. W. Lancaster.
Fire-arms, breech loading—987—A. Muir.
Forks, cleansing and polishing of—950—C. Martin.
Gas, regulating the supply of—972—C. Esplin.
Gr in, apparatus for threshing, &c.—742—J. Marshall.
Hammock, portable covered—894—T. W. Nordenfett.
Hay, straw, &c., machines for cutting—934—R. R. Riches and C. J. Watts.
Heat or cold, preventing the transmission of—864—F. Le Roy.
Inking rollers, manufacture of—914—A. V. Newton.
Iron ships, &c., protecting from oxidation—970—E. Ritherdon.
Kitchen ranges—940—F. Brown.
Lamps, reflectors for—897—B. Baugh.
Lighthouses, apparatus for illuminating—945—J. E. Wigham.
Locks—999—N. G. Kimberley.
Looms—928—A. W. Pearce.
Matches, &c., frame silling machines for—1003—H. J. Simlick.
Motive power, apparatus for obtaining—3140—W. A. Turner and T. T. Coughlin.
Musical instruments, stringing and tuning—954—W. Moody and W. J. Huband.
Nut crackers, &c., handles of—993—T. White.
Oil and grease, lubricating—966—W. Teall, L. Lepaige, and E. T. Simpson.
Ornamenting metal tubes, machinery for—924—G. Burt.

- Photograph cameras—1009—V. A. Prost.
Photographic images, production of—712—R. A. Brooman.
Postage stamps, &c., manufacture of—936—J. H. Johnson.
Projectiles and cartridges—932—J. von der Poppenburg.
Railway breaks—745—H. A. Bonneville.
Railway carriages, &c., stopping or retarding—1021—G. Voigt.
Railway trains, communication between the guard and passengers of—858—H. J. Walduck.
Railway trains, communication between the passengers and guard of—929—J. C. Stovin.
Safes, construction of—904—T. Cook.
Safes, manufacture of—685—S. Chatwood.
Safes, securing the doors of—946—G. C. Thompson.
Sewing machines—848—E. H. Smith.
Sewing machines, binding attachments for—601—H. E. Clifton and A. Hoffnung.
Shaping machines—896—W. M. Neilson.
Shot, shell, &c., rounding and polishing—952—W. Clark.
Sizing paper—1005—W. Weatherley.
Soda and potash, manufacture of—1011—A. G. Hunter.
Steam boilers—906—J. D. B., and O. Svarbrick.
Steam cultivation—956—W. Bulstrode.
Straw, apparatus for reducing—985—R. Garrett, jun.
Telegraphic apparatus—910—H. A. Bonneville.
Toast racks, manufacture of—811—J. Burley and L. Glover.
Vegetable materials, separating fibre from—958—G. T. Bousfield.
Washing machines—605—H. A. Bonneville.
Weights, safety tackle for raising—937—P. J. Jamet.
Yarns or threads, machinery for finishing—1019—R. Ferguson and W. Ralston.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

- Mineral oils, lamps for burning—1040—C. Boschan, J. Binstler, and W. Caffau.
Vessels, connecting a gaff to the mast of—1067—C. R. Fisher.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MAY 10.—"On the Art of Laying Submarine Cables from Ships." By Captain JASPER SELWYN, R.N.

MAY 17.—"On the Manufacture of Encaustic Tiles and Ceramic Ornamentation by Machinery." By ZERAH COBURN, Esq.

CANTOR LECTURES.

The Third Course for the present Session, consisting of six Lectures, "On Some of the Most important Chemical Discoveries made within the last Two Years," by Dr. F. GRACE CALVERT, F.R.S., F.C.S. (Corresponding Member of the Royal Academy of Turin; of the Société Industrielle de Mulhouse; of the Société Impériale de Pharmacie de Paris, &c.), is now being delivered on Tuesday evenings, at Eight o'clock, as follows :—

MAY 9TH.—LECTURE 5.—On the Discoveries in the Chemistry of Rocks and Minerals.

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

Proceedings of the Society.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 3, 1865; M. H. Marsh, Esq., M.P., Vice-President of the Society, in the chair.

The following candidates were balloted for and duly elected members of the Society :—

Balforn, John Edward, 6, The Lawn, Shepherd's-bush, W.
Bedder, William, Saltash, Cornwall.
Borochitzky, J. F., 32, Tavistock-place, W.C.

Botly, William, Salisbury Villa, Upper Norwood, S.
Buckley, R. S., Mossley, by Manchester.
Clever, Joseph, 7, Coleman-street, E.C.
Cozens, Samuel E., Phoenix Wharf, Southwark, S.E.
Davison, Thomas Langmore, 2, Lavender-terrace, Lavender-hill, S.W.
Edwards, Samuel, 13, Limes-grove, Lewisham, S.E.
Green, John, 2, Gloucester-place, Lower Tulse-hill, S.
Hawks, John, 3, Brockley-villas, Brockley-road, Newcross, S.E.
McClellan, Samuel, 7, Cambridge-terrace, Upper Lewisham-road, S.E.
Shanks, James, St. Helen's, Lancashire.
Skelton, John, jun., M.D., 105, Great Russell-street, W.C.
Taplin, Thomas, 14, St. James's-square, S.W.
Westhead, Albert, 20, George-street, Hanover-square, W.
Westhead, Edwd. S., 20, George-street, Hanover-sq., W.
Wilkinson, T. L., 1, York-villas, Sydenham-park, S.E.
Wynne, F. Osborne, Archcliffe Fort, Dover.

The Paper read was—

ON COLONIZATION: ITS ASPECTS AND RESULTS.

By WILLIAM STONES, Esq.

Having had the honour, a few years ago, of submitting to this Society a short notice of the colony of New Zealand, which led the way, I believe, to the reading of several very interesting papers treating of the colonies of Canada, the Cape of Good Hope, Mauritius, and a most important contribution by Dr. Forbes Watson on Indian matters, it has occurred to me that the Society might follow up the subject, and advantageously occupy an evening in the discussion of several topics not appertaining to any one colony in particular, but in connection with colonisation generally.

The short time at our command, and the space in the *Journal* to which I am limited, compel me to suppress several subjects possessing some interest, and, therefore, I pass over all reference to the different forms of ancient and modern colonisation—the aspect of colonisation in its relation to the religious institutions of England—to our literature—to English amusements—to the important question of the effects of colonisation on other races, whether slavery, extermination, or incorporation—and, lastly, to another interesting subject, the peculiar genius of Englishmen for colonising. All these on the present occasion must be omitted.

Limiting our views to the British colonies and dependencies, we may notice their number, situation, and climate. Stretching almost entirely round the globe—extending from the nearest habitable land to the north pole, through the tropics to the Falkland Islands and New Zealand in the southern hemisphere, every variety of climate, position, and production is included within the limits of the British Dominions.

Parts of all the great continents are held by Great Britain—as Canada, in North America; Honduras and British Guiana, in South America. In Africa, besides the stations of the Gambia, Gold Coast, and Sierra Leone, we have the colonies proper of the Cape of Good Hope and Natal. By our magnificent Indian Empire, Singapore, and the treaty ports of China, Asia is, to a great extent, brought under British control; while the whole continent of Australia (and I presume it may take rank as one of the five great powers) is entirely under British government. On the Continent of Europe, after all our wars and expenditure, we retain but one little spot—the coveted stronghold of Gibraltar, the key of the Mediterranean.

As a seafaring insular people, it might be supposed that we should have a natural bias or inclination to form settlements on islands; and beginning from Heligoland and the Channel Islands at our own doors, we shall find, if we trace along the subjoined sketch map, islands without number hoisting the British flag.

We note Newfoundland, Prince Edward's Island, the Bermudas, Bahamas, the West India group, Falkland Islands, St. Helena, Mauritius, Ceylon, Singapore, Hong Kong, a station in Labuan, Van Dieman's Land, and the cluster of islands known as the colony of New Zealand, and, lastly, Vancouver's Island—and Malta, in the Mediterranean; but it is quite beyond my power to accurately reckon the number of islands claimed by England, as many of those I have named include several small satellites under their government.

Not less various are the climates—Canada, with its six months of frost, snow, and ice, massive, grand, and solemn in its features, bracing and exhilarating to her hardy inhabitants; the seething plains of India, suggesting disease of liver, brevity of life, and quickness of fortune; the milder climate of Australia, where health is so good that doctors find small encouragement, and frost is little seen or felt; the clearness of the Cape, where twenty oxen, slowly toiling, drag the farmer's waggon over the sandy soil, baking, broiling, dry, yet healthy; or the foggy coasts of Newfoundland. And here we may call attention to the difference which exists in climate between the two coasts of North America. The isothermal line of 50 deg. Fahrenheit enters the German Ocean in about 53 degrees north; it reaches its highest point in the British Isles, where it touches the parallel of 54 deg. north; after this it bends southward, until, on entering the American continent, it descends to the low latitude of 40 deg. north. In its course across America its defection is on the whole northerly, and on the eastern side it again reaches to 54 deg. north.

The eastern sides of the Atlantic and Pacific Oceans are warmer, and the western sides colder, than is due to latitude merely. This fact was noticed by Captain Cook, and is owing to the cold polar waters washing the coast of Canada and China, while the warm streams from the tropics flow on to the coasts of England and Norway in the eastern hemisphere, and Vancouver's Island and British Columbia on the west coast of America. Hence, British Columbia and Vancouver's Island have much milder winters than places in Canada under the same parallel of latitude.

Rivers.—Some of the colonies and dependencies have large rivers, as the St. Lawrence, whose vast watercourse forms the great outlet of the magnificent chain of lakes or inland seas of North America. India, with its sacred mythical rivers, carrying us in thought back beyond the reach of authentic history; and the islands of New Zealand,

land, which are pierced in every direction by numerous navigable streams. On the other hand, some of our largest colonies are almost totally deficient of rivers, as those on the great continent of Australia, in which railways must be relied upon to provide inland carriage.

Of harbours, we may boast the unrivalled Halifax and Sydney—one in each hemisphere—only perhaps exceeded in beauty by that of Rio de Janeiro.

Productions.—We shall hereafter refer to the variety of productions more in detail, suffice now to say that, in 1862, Canada sent us timber to the value of £1,237,689; that upwards of 2½ millions of sheep grew wool for us in Australia and New Zealand; and our own colonies of Australia and Vancouver's Island produced £8,000,000 of gold; while, of colonial sugar, we imported to the value of upwards of two millions.

Variety of Population, Religions, and Laws.—From the circumstance of so many of our colonies having been acquired by conquest, it almost necessarily follows that we must have a many-toned and hued population subject to British rule. We can only mention the French in Canada and the Mauritius, Dutch at the Cape, African blacks in the West Indies and in Africa, Hindoos, Chinese, Malays, Australians, New Zealanders. Nor are the religions less diverse—Protestant, Catholic, Mahomedan, Hindoo, Parsee, savages who believe in wood and stone images, and savages who have hardly risen to any idea of a God at all. Equally various are the systems of law in force—British law, Code Napoleon, local laws, and heathen customs, so long as they are not repugnant to good citizenship, are left tolerably free to their own workings.

Amongst all these varied peoples, tongues, colours, customs, and habits, British rule has, we believe, resulted in two profound convictions and enjoyments—a sense of perfect protection of person and property, and freedom of thought and action.

Acquisition.—Inspection of the accompanying table will at once show the very varying modes in which this country has obtained its colonies and dependencies. The column “mode of acquisition” testifies to many a hard-fought battle by sea and land. The tale of Wolfe's battle of the Heights of Abraham, or the attack and siege of Gibraltar, cannot be read at this distance of time without feelings of glowing pride. Every West India island has its tale of courageous attack or sagacious defence. And those which tell of less warlike deeds are not without their interest from another point of view. We owe our acquaintance with them to the privations, patient endurance, skill, energy, and genius of such bold, self-reliant men as Cook, who, in vessels not larger than a moderate-sized yacht (the *Investigator* we all recollect lying off our hall of meeting until within the last few years, doing good service in her last days in the humble form of a Thames Police-station), sailed into unknown seas at the Antipodes, tracked and surveyed the strange coasts, returning home with important results, and contributing largely to the geographical and scientific knowledge, and high moral position of his native country. So judiciously did he conduct his explorations and communications with savage tribes that his name is still remembered in the South Seas as the introducer of various animals and vegetables with which the people were previously unacquainted, and the name of Cook is revered as their kind and courteous benefactor. No one ever heard in those regions a whisper against his fair fame.

SOCIAL ASPECTS.

Few rich people emigrate; few with a good commercial opening before them leave the land of their birth. Strivers amongst the middle classes, younger sons, poor and labouring men, principally the latter, are the classes of which emigrants principally are and should be composed—men with restriction of field at home and small margin between income and necessary expenditure. The two aspects of colonisation from a social point of view, which I wish prominently to bring before you, are—

1st. The direct benefit to the emigrant; and 2nd. The indirect benefit to the home-stayer.

The Emigrant.—A competent workman no sooner arrives in any of the colonies than he finds ready and full employment at wages which, if economical and provident in his habits, leave him a large margin between income and outgoings. Taking the agricultural as the lowest type and worst paid of English workmen, the farm labourer on reaching a colony obtains for his work both money payment and ample rations, the former alone generally averaging more than his total highest remuneration at home. He is thus at once relieved from all care on the subject of procuring food. Meat, which in England he tasted perhaps once a week only, he now has every day, and three times a day if he likes; and the weekly wages, which in England had to provide him with food, housing, and clothes, can now be devoted to the purchase of luxuries, or, if prudent, by saving a portion of his income for a time, he can soon reach a position enabling him either to buy a small plot of land for himself, which he can always obtain for a few shillings per acre, or to join in the renting of a sheep-run on shares, thus laying the foundation of a fortune. A few years of more or less rude success, during which the emigrant has learnt self-reliance, and he, who would probably have passed his life at home as a mechanic, or, perchance, risen to the dignity of a foreman, and unless by special fortune never attained to any social or political importance, perhaps never possessed a vote, becomes in the colony a person of means, can afford to purchase a good house, good furniture, to live well, even luxuriously, is entitled to vote for local officials and the legislature, enters into the discussion of public matters, and gradually comes to have an opinion of his own, which he enunciates in the press or in speeches at public meetings, and every little place has its newspaper, in which argumentative colonists carry on their discussions. These discussions determine his choice of a member for the legislature, if himself desirous of remaining a simple citizen, but if ambitious, he feels that no impediment exists to his becoming a legislator himself. With character and sufficient education he may succeed in leading a local assembly, but if limited in his oratorical powers he must be content to be a silent member, though not the less useful. Thus men, whose whole life would probably have been restricted to the questions of daily wages and the propriety of strikes, or a low murmur about their exclusion from electoral rights, gradually open their minds to questions of revenue, taxation, political freedom, colonial rights, exploration, harbours, fisheries, boundaries, settlements, education, the improvement of estates, and the general public good. These briefly are some of the advantages which accrue to those who emigrate.

Home-stayers.—The advantages to those who remain at home are numerous, although apparently less direct. First, there is the withdrawal of a large per-centage of competitors from the labour market. The law of supply and demand obtains, in the case of labour, as in that of other commodities. If a given number of employers have need for, say nine men, and ten workmen apply for the work, the employer will reduce the wages of all the nine required to the lowest possible amount; the labourers, in fact, compete with one another as to which one shall be left out of work; but if the employers have work for nine men, and only eight are obtainable, the employers compete with one another for the services of the men by offering inducements, generally in the form of increasing their wages. Hence, the importance of emigration, from a labourer's point of view—transferring the competition from the shoulders of the workman to those of the master. That this has been the case during the last ten or fifteen years will be evident, if we investigate the present rate of agricultural wages, and compare it with the rate which prevailed at the former period. I am aware that another cause besides emigration has been operating in the direction to raise wages—I refer to the introduction of machinery into agricultural pursuits. When threshing

was done by manual labour, one man was almost as good as another, but the man who can drive, stoke, or feed a threshing-machine is no longer a common labourer, but a skilled workman; and unless his wages be raised above those of a mere labourer he will speedily seek some other engagement—his intelligence, his mind, must be paid for. With a diminution of demand, fewer permanent hands being now required upon farms, the great reason for wages being higher at the present time than formerly, can only be from the fact of large draughts of men having been enticed from England by the prospect opening to them in our colonies, and by that means withdrawn from the home-labour market.

Number of Emigrants from the United Kingdom, distinguishing the Nationality and Destination, for the Year 1862.

Destination of Emigrants.	Year.	English.	Scottish.	Irish.	Foreigners.	Not distinguished.	Total.
United States	1862	14,180	1,025	33,521	2,338	7,592	58,706
Brit. North America ..	"	2,578	2,645	3,107	137	7,057	16,522
Australian Colonies ..	"	17,827	8,599	12,402	682	2,383	41,943
Other places	"	904	327	680	134	3,123	5,143
Total	"	36,687	12,596	49,690	3,311	20,149	121,314

From Mr. Morton's paper, read before this Society on 8th December, 1859, it appears that the wages of agricultural labourers throughout Great Britain have risen, on an average, about 20 per cent. between the years 1849 and 1859. All this proves, says Mr. Morton, that the labouring force in agriculture is better paid than it used to be, and that the enormous extension of machinery and of steam power lately has not been to the injury of the farm labourer.

Not only have wages been largely improved by emigration, but there is another point of influence upon social life which must not pass without mention. Speak to a person in whatever sphere of life we may, it will be almost instantly ascertained that a brother, sister, relative, or intimate friend is settled in some distant colony; and with such emigrants the dwellers at home keep up a correspondence more or less regular, bringing about a knowledge of the world and its varying interests vastly different from that which obtained only a few years ago, when it was not unusual to meet with persons whose geographical knowledge was bounded by the limits of their native village or town. I speak a fact when I say that within the last twenty years I have myself conversed with a country resident, the proprietor of the farm he cultivated, who, living within 25 miles of a railway and a seaport, to which steamers were running daily, had never seen either a railway, a locomotive, or a steam-vessel, and all my attempts at explanation utterly broke down when I found that his utmost idea of a steam vessel's mode of propulsion was by sweeps, as he termed them, similar, as he supposed, to the small oars of a boat on the mill pond. The views of the world which the emigrant obtains are scarcely less different than the expansion which is taking place in the minds of the home stayers on the great interests which affect our country. Further, every man who emigrates may be said to support one at home, by becoming a purchaser of English manufactured goods, and thus are the home-stayers benefited; to how large an extent will be more apparent when we have treated of the commercial results of our colonies. In fine, the physical, moral, and social condition of both these two great parties to which we have referred is rapidly changing and, I believe, improving. Two little incidents which, from their coming under my own notice, I may relate as bearing on this part of the subject. In the depth of a bitter winter, a group of labouring men were huddling round an inn fire, at which they were kindly permitted by the host to warm themselves, and, on

inquiring as to the cause of so many able-bodied men lounging about, I was informed that they could not get work, and were not allowed to go into the Union until they had been out of employment six weeks. They added that there were forty men in the like distress in that parish, a purely agricultural one, the coveted wages when in full work, for which they were so anxious, being some 8s. per week. Incendiary fires were frequent that autumn and winter; if my memory serves me correctly, eight were counted in my evening walks during one and the same week. Is it not appalling to reflect upon such a state of things? Starving men burning abundance. In my own mind, I have often contrasted this sad condition of matters with the cheering prospects indicated in the following simple tale, for the accuracy of which I also vouch. When I was in one of our colonies, an Irish emigrant once solicited me to write a letter for him to an old friend at home, which I assented to do. "Tell him," said he, "that if he has not plenty of work to come out. Tell him we came out safely and comfortably. Tell him, sir, it is a beautiful country. Tell him there is plenty of work here;" and then he related various domestic pieces of intelligence as to the increase of his family, &c. "Well," said I, after penning all the subjects as he dictated them, "anything more?" Considering awhile, he said, "Nothing, your honour, thank ye;" but, recollecting himself, added, "Oh, please, tell him there is plenty of pork and potatoes." A great truth lurks under this last sentence, for our physical well-being is at the foundation of all civilization, science, art, and the amenities of life.

WHO SHOULD EMIGRATE.

This leads me to offer a few remarks on the great question—Shall I emigrate? Every person falls into one of two classes, desirable or dead-weights. Men with families, likely to settle down permanently and become the backbone of the colonies, are desirable, and if possessed of moderate capital, so much the better. Very desirable colonists are those working men who have a sound knowledge of some handicraft, as bricklayers, carpenters, masons, blacksmiths. Farm labourers, shepherds, are also valuable; and subordinate to these, all men enjoying good health, and able to do a hard day's work of any rough kind. Of the female class we should like a supply of country domestic servants, and handy lasses, knowing how to milk, wash, and iron, boil a potato, make a pudding, and roast a joint. To such we should be quite willing to give high wages as long as we could keep them from the allurements of some prosperous mechanic or successful farmer. Speaking as a colonist, I may say there are whole groups of people we do not want and would much rather be without. Of professional men we have more than enough. Legal men are so abundant at home, and the chances of great success so uncertain and rare, that no wonder the overflowings of the profession seek to obtain advantage of every opening possible in the colonies. Again, when it is remembered that every emigrant vessel must carry a surgeon, it will at once be seen how superabundant must be the members of that profession in some of the colonies. 40,000 emigrants go to Australia every year, conveyed in 160 or 200 ships, and as many of the surgeons do not return, but remain in the colonies, we may form some idea of the yearly addition to the medical branch of the community. The needlewomen, the sempstresses class, are not of value to us; accustomed to town life, weak, feeble, unenergetic, not used to domestic work, they find little occupation, and are a burthen to us. For young men who have not learnt a trade, men of the pen only, we have but little room; there is always a large supply on hand, and as living is comparatively dearer than at home, they are the most disadvantageously placed of any class in the colonies. They know no trade or handicraft, and are, as a rule, physically unable to do laborious work, and therefore are far worse off than the commonest unskilled labourer. One morning, not long ago, a young man called upon me with a note of introduction, and informed me that he was

desirous of my opinion on the subject of his emigrating. From his somewhat worn aspect and the aroma of strong tobacco which environed him, I was rather puzzled how to advise him, and therefore requested him to state his own views, projects, and ideas, so that I might confirm his plans or suggest some deviation. Judge my astonishment when I heard his first question, "What hats would you advise me to take?" "To sell?" said I. "Oh, no; to wear." Without meaning a pun or innuendo, I could not avoid saying, "A wide-a-wake." I need scarcely add, that young gentlemen who are very particular about the sort of hat they should wear, we do not much require.

COMMERCIAL ASPECTS AND RESULTS.

It is worthy of note that for the supply of the staples of our principal manufactures we, at the present time, mainly rely upon our own colonies and dependencies. The following very brief reference to a few of the principal items may suggest rather than fully demonstrate the extent of our transactions in this respect:—

Timber.—For timber we largely resort to Canada, New Brunswick, and Nova Scotia, whence we imported, in 1862, no less than to the value of upwards of three millions sterling. Mahogany is obtained from Honduras, and teak we obtain from our Indian possessions.

Cotton.—The cultivation of cotton has so far progressed in our own dominions, more especially since the war in the United States, that the import value in 1862 from purely British possessions, was no less than eleven millions sterling.

Wool.—For the important staple of our wool manufactures we now, to a very great extent, depend upon the vast pasture lands of Australia, the Cape of Good Hope, and Natal; the total value of the wool produce of these colonies being now estimated at £6,832,578 per annum.

Fish forms a large article of trade and export from some of our North American colonies, to a greater extent than most of us would suppose, viz., £1,450,000 yearly.

Sugar.—We imported from our West India Islands, the East Indies, and the Mauritius, to the value of nearly £3,500,000.

Gold.—All will recollect seeing in the Exhibition of 1862 the pyramid representing the mass of gold obtained from Australia since the discovery of that precious metal there in 1851. The pile represented many millions sterling, more than ever came into the possession of Croesus or the desire of Midas.

TOTAL GOLD PRODUCTIONS FROM 1850 TO 1863 INCLUSIVE.

Old Sources	£202,793,000
British Columbia	5,605,000
Australia and New Zealand	136,388,000
California and United States	142,200,000
Other Countries	1,018,000

Total..... £488,004,000

These most important and valuable items of our colonial commerce are for the most part either the unassisted productions of nature, needing but the rudest kind of labour to extract them from their sites, or prepare them for the market, or otherwise requiring but the simplest form of attention as sheep farming, and chiefly depending upon the mild equable character of the climate for successful and profitable results. Let me here call attention to the following return of exports from our colonies, extracted from the Board of Trade Returns for 1862:—

EXPORTS FROM THE COLONIES AND DEPENDENCIES, 1863.

Cotton	£10,208,470
Coffee	2,141,810
Fish	1,450,819
Gold	8,799,558
Rum	553,177
Sugar	6,600,232
Wood and timber ...	3,268,044
Wool	8,305,152
Principally sent to Great Britain.	

How are these mighty heaps of raw produce paid for by the mother country? Chiefly, if not entirely, by its manufactures.

In a populous country only the most skilled workman has at all any chance of success; the mere manual labourer remains, as a rule, in his routine sphere of everlasting grinding work; but in a new country the most ordinary, least-skilled labourer rises into a condition of hope, and by his largely-increased wages, can and does become a great consumer of English manufactured goods. As a general principle, it is cheaper and better for the colonies to send home their raw materials to be prepared by the skill, machinery, and appliances of England, and re-import the manufactured goods, than attempt to work up the raw material in the colonies. The abundance of coal, the perfection of machinery, and the cheapness of labour, all tend to secure this result in the most economical manner; hence the wisest of the colonial governments look for their continued prosperity rather than the still further development of their unexhausted, and, in many cases, almost inexhaustible natural resources, than to the introduction of manufactures.

The necessary revenue is generally raised by a moderate import duty upon the principal articles of consumption, by an export duty upon some articles of great production, assisted by the proceeds of the sale of government waste lands. A few of the colonial legislatures have unwisely increased the import duty upon some articles, even more with a view to protect their incipient manufactures than for strictly revenue purposes, thereby artificially raising, to the injury of all, the price of the highly-taxed article for the benefit of the very few colonists who may enter into the manufacture of the goods thus selected for special taxation. This course is a great wrong to the body of colonists and most injurious to the English manufacturers, who help to pay the taxes—increased for the defence of the colonies—and we plainly state to our colonial friends that this short-sighted policy is bearing and will bear bitter fruits for them in all discussions of colonial questions. Not many have adopted a tariff of this kind, and obviously such a course is contrary to the first principles of political economy.

Disregarding these pernicious exceptions, we may say, speaking generally, that in return for the raw materials supplied by the colonies the mother country pays in manufactured goods of all kinds. In proof of this we have only to refer to the list of exports, from which it will be seen what extensive customers our colonies annually are to the mother country.

EXPORTS OF BRITISH AND IRISH PRODUCE AND MANUFACTURES.

The following is an account of the declared value of British and Irish produce and manufactures exported from the United Kingdom to each British possession in the year 1864:—

Heligoland	£. 15
Channel Islands	1,016,171
Gibraltar*	1,206,206
Malta and Gozo	746,386
Ionian Islands (ceded to the Kingdom of Greece June 2, 1864)	110,238
Western Africa (British)	269,173
Ascension	10,303
St. Helena	34,542
Cape of Good Hope	1,814,877
Kaffraria	29,365
Natal	428,135
Mauritius	658,259
Aden	31,758

* The return for Gibraltar must, I should suppose, have some mysterious connection with Spanish smuggling, or is it purely as the dépôt of the Barbary States that it figures so high.

India:—Bombay and Scinde	9,176,386
Madras	1,590,233
Bengal and Pegu	9,128,626
Singapore and the Eastern Straits ..	1,185,680
Ceylon	828,368
Hong Kong	1,610,957
Australia:—West Australia	97,596
South Australia	1,116,767
Victoria	5,316,933
New South Wales	2,742,780
Queensland	451,365
Tasmania	266,926
New Zealand	1,866,312
British North America	5,611,276
Bermudas	656,777
British West India Islands	2,659,778
British Guiana	803,503
Belize (British Honduras)	205,015
Falkland Islands	12,826

Total to British Possessions... 51,683,430

Several other points of commercial interest, deserve a short notice in this review.

Ship-building.—At the earlier period of our colonial history, ships were small, their provisioning bad and scanty, the water disgusting, voyages long and tedious. As the number of emigrants increased, it became advisable to enlarge the size of the ships, which brought another view into the consideration of the owners—the shorter the passage the less provisions would be consumed, and hence the shipowner came to have a direct interest in lessening the duration of the passage to the lowest possible period, as the value of every day's provisions for three or four hundred persons amounts to a considerable sum. Hence sprang improvements in ship-building, and increased attention to the routes, great circle sailing, and observations of the trade winds, the best points for crossing the line so as to avoid delay from calms, the importance of making southing as fast as possible, to lessen the length of the degrees of longitude, &c. As a rough approximate rule, it may be taken that a ship of 400 tons register would be 110 days making the passage to Australia, and every increase of 100 tons in burden would decrease the passage two days, or for each enlargement of 50 tons, one day less in the passage may be reckoned; if this is approximately correct, a vessel of 1500 tons register would make the passage in 88 days.

The legal enactments for the provisioning both of poor emigrants and sailors have tended very much to the comfort of all; and whereas disease, particularly scurvy, formerly destroyed large numbers of our seamen, we seldom hear of a case of total or even serious attack of that malady. So far from the long voyage being now hurtful to the health of the emigrants, this generally improves on the passage—they have no pressing anxieties, are well and regularly fed, breathe the fresh invigorating sea air, and have an ever present medical attendant in case of sickness.

Our principal steam packet companies owe their development to the necessities of our colonial intercourse rather than to foreign trade. Nor ought we to omit noticing the vast strides which steam ship-building has taken, not only for the requirements of main ocean lines, but in every part of the world. On local lines of traffic, steam vessels built in the Thames, Mersey, and Clyde, are daily coasting the shores of India, New Zealand, and Australia, and the two widely separated coasts of British North America, driven by men of English northern tongue; some may be, like Albert Smith's engineer, enduring and fattening upon a grievance, but for the most part all doing their duty honestly and thoroughly as Englishmen should.

Banks and Monetary Interests.—Another important commercial interest is that connected with banking and monetary affairs. Some of our most prosperous banking

institutions have their principal seats or spheres of action in our colonies and dependencies. Their uniformly sound management causes them to furnish safe investments for English capitalists, and the high rate of interest in the colonies enables them to pay large dividends regularly. From the columns of the *Economist* I have compiled the following schedule, which, necessarily imperfect, as it only includes those which have agencies or branches in England, may illustrate rather than exhibit the vast monetary interests which open fields for investment in connection with our colonies. Some of the great loans are guaranteed by the British Government, and the money raised has generally been honestly applied to the furtherance of the true interests of the colony.

(Want of space will only allow of the totals being given.)

	GRAND TOTAL.
Stock, Loans	£50,236,093
Railways	78,899,635
Banks, Insurance, and Miscellaneous Companies	44,823,737
Total.....	£173,959,465

Hence we have engagements for the great total of one hundred and seventy-four millions sterling, invested under the laws of our own country, and in many instances guaranteed either by the Colonial or Indian Governments, and in some cases by the Home Government, yielding at an average rate say of 7½ per cent. per annum, an income or profit to the investors of thirteen millions, without fear of repudiation or revolution.

Postage, Telegraphs, Railways.—The enormous dimensions of our overseas postal system are largely owing to the increase of population in our colonies. I would merely remind you that in almost every day's *Times* you may read of vessels from the east or west with so many passengers and, without exaggeration, letters numbering up to hundreds of boxes. These hundreds of boxes contain thousands of messages of goodwill towards men—cheerful, loving words from children to parents—remittances of comfort to the old folks—family gossip and the effusions of affection borne on the waters from afar to many cottage homes in the land.

Telegraphs either have been laid down, or are in course of construction, from England to India, from one colony of Australia to another—thousands of miles in length—from one end of New Zealand to the other—and all through Canada. The gigantic efforts now contemplated a second time to span the Atlantic by a telegraphic cable, will if successful, connect the mother country with the outlying picket, if I may so say, of her American offspring. And while actually writing these sentences a telegraphic message comes from Bombay to London in a very few hours, and we have news from Melbourne in 28 days.

A whole evening might be advantageously devoted to the consideration of colonial railways—whether the Grand Trunk Railway, with its colossal bridge, and although perhaps born before its time, the true type of a main line, some 1,200 miles in length, running through and serving a whole country—or those spreading lines through every colony, joining towns and districts and annihilating distance—or those most important lines in India, enabling the produce of the interior to reach the shipping ports at a small charge, and, what is even more unexpected and astonishing, breaking down the distinctions of caste, all castes meeting on the common and neutral ground of the same railway carriage. The preceding statement of outlay on railways better expresses their importance than any observations our limits on this occasion will admit.

Machinery and the Fine Arts.—For machinery of all kinds our mechanical engineers find their most regular

and profitable demand is for exportation to the colonies. Steam machinery of every description, agricultural implements, mill-work, guns, metal work, electro-metallurgy, and work in the precious metals, jewellery, watches, clocks, glass, and furniture of the more expensive kind, all find their more or less prominent place in our colonial export trade.

TRANSPORTATION.

The objects of criminal treatment are twofold—to secure the community by deterring the evil-disposed, and to reform the fallen. In order to deter, punishments should be uniform, moderate, and certain, which unfortunately has not been the case with our English system, in which punishment has been irregular, and unequally inflicted in amount, and most uncertain in duration. This aspect of punishment concerns the criminal only so far as enabling him to speculate and rejoice at the chance of immunity; it is within the power of the community to rectify these errors, and it is beyond a province to enter into that discussion; our subject regards transportation from the colonist's point of view. Many of our colonies were founded for penal purposes, and such public buildings, important clearings, and a great deal of most useful rough work, have been constructed and accomplished by convicts, farmed out to the settlers, receiving food and clothing in return for their labour, thus placing the free colonists in the position of enjoying the results of unpaid labour without the capital outlay for slaves. As emigrants increase, and colonies obtain the advantage of the competition of free labour, it is obvious that not only is the stigma of convictism disagreeable, but the free community of labourers will object to the presence of competitors of the tainted class. If, then, the colonies will not have our convicts, we must either let them loose at home under some sort of control, or keep them in confinement. Tickets of leave, in an old country, are sources of unmitigated evil, both to the free workman and the convict; if a convict is accepted to his prejudice, the former infers that virtue goes for nothing with employers, and those who may be required to work with tickets of leave must either give up their employment or lower their tone of morals by associating at the same bench with convicted thieves and murderers. The convict also finds himself exposed to such a terrific competition that he seldom succeeds, and generally returns to his old courses. Must we, then, shut them up within four walls, with the society but that of their own sex, hardening and brutalising their already degraded being?—a treatment certainly not in accordance with man's nature, or the laws which are stamped upon the universe. By allowing a criminal to obtain a reduction of his term as the result of a religious change, the doorway was opened to his being again let loose upon society, and this tempted him to become a hypocrite. The tendency of recently-improved legislation is to make him a suicide or a maniac. Will hope can any man have who is doomed to be immured within prison walls for ten long years? It is a living death; or worse; and one of the most humanising instincts of nature—the family—is altogether lost sight of. What do you propose to do with their wives? Will you release these wretched women from their marriage ties? And although a rigid law may say it has nothing to do with that, the instinct of nature echoing the law of God has something to do with this matter. As, then, man within four prison walls can have but little hope, and you thereby destroy the most softening influence of his nature, is there any other way by which you can equally as well secure the absence of the convict from society and yet not entirely destroy hope? All who have been in the colonies will recollect that, in the days of transportation, it was not at all an unfrequent occurrence for the wife of a convict to follow him; in many cases the husband was apportioned to his wife as her assigned servant, and circumstances being favourable, they frequently reached a respectable position to which they not only could never have had the slightest chance of attaining, but would probably never

* Through the Post-office alone remittances were sent in 1862 by settlers to their friends in Great Britain—From North America, £381,901; from Australia, £81,123.

have thought of attempting in the mother country. Many ticket-of-leave men would reform if they could, but they have not and never can have an opportunity for restoration in England; they have no honest mode of life open to them. What shall be done with them, then? The Falkland Islands appear to me suitable for the formation of a penal settlement. They are sparsely inhabited, escape would not be easy, and the climate is not severe. Some of the agricultural class of convicts might be allowed to settle upon small garden farms, and work out the payment by the produce; others might usefully employ themselves in those occupations which they might be previously taught in the home prisons, as tailoring, shoemaking, carpentry, blacksmithing, &c. Good behaviour for a term might entitle them to send for their wives, and thus some ray of hope of constructing a family be held out to them; and a face to face grapple with nature, albeit rough and stormy, would be more likely to improve and elevate the man, when brightened by hope, than the morbid influences of imprisonment.

ADVANTAGES OF COLONIZATION.

The surface of Great Britain being limited it follows that, as the population increases, the capacity of the land, if devoted to purely agricultural purposes, would soon be overtaken and eventually surpassed.

The needs of a large and increasing population can only then be met by increasing the non-agricultural proportion of those who remain in England and by transplanting others.

In 1861, the population per thousand appears to have been composed of

- 24 Professional.
- 574 Domestic.
- 31 Commercial.
- 101 Agricultural.
- 242 Industrial.
- 28 Not defined.

1,000

It would seem, then, that as the quantity of land cannot be enlarged, the agricultural class must remain stationary in numbers or diminish, which latter is the more likely to be the case from the improved mechanical appliances brought into use for the cultivation of the soil, and it is within possibility that the industrial, which even now is more than double the agricultural, might eventually become too productive for the needs of its own limited community. The endeavour, therefore, of all sound statesmanship should be to adjust the demand to the production, and by such encouragement of emigration lead to the growth of purchasers in some measure proportionate to the necessary increase of manufactures.

Our colonies afford this plantation or nursery-ground for the growth of purchasers, the aggregate of the land available being, according to the table at page 414, practically unlimited, and the home deficiency of area is thus amply compensated by the extent of our colonial possessions. Another advantage of having so large an extent of acreage, in the form of colonies, is that the emigrants do not remove from the laws and manners to which they have been accustomed; they convey with them, and find on arrival, the same political, religious, and social thoughts and habits. Similar climate, area, and soil, would not be so advantageous, if the emigrants felt that they were going to a country under a despotic government, or one where the laws would be found to differ much from those of the land they had left. The tastes and habits of the emigrants having been acquired in England, they, to a great extent, lead to a demand for home productions for their gratification, a very important matter in a commercial point of view.

A third great advantage derived from the colonies is the sphere they afford for the prosecution of theoretical

and practical science. And here multitudinous names, crowd upon the memory. One dare hardly individualise for fear that the very next moment the name of a second equally bright star may shoot across the sky.

Let me remind you how much we owe to Captain Cook pre-eminently, to Banks, and Solander, and that our most learned botanist, Robert Brown spent years in Australia; the speculative Darwin, whose views are shaking the scientific world, studied the coral reefs when out amongst the Australian colonies. The names of Beete Jukes, Logan, Bennett, Falconer, Hooker, and Huxley are symbols of legions of similar worthies, whose bold, broad philosophy has been to a great extent the result of the open eye due to the deep questioning of nature in her various forms in our new colonies. India opened out new fields for botanical research; Australia disclosed an entirely new series of animal life; and Canada has afforded a magnificent field to our geologists, the earliest form of animal life on our globe having been there recently discovered in a stratum far below that in which life had been previously observed.

And for practical science how vast the field. The marine of the country is employed and developed in the form of large emigrant vessels and coasters to the incredible extent of many millions of tons. Need I do more than call attention to the innumerable surveyors, engineers, architects, and educators who find ample scope and remuneration for their talents in the colonies. The surveys and canals of India, the railway and bridges of Canada, the road, harbour, dock, telegraph, and mill works in every latitude and longitude witness to the enlarged school of mechanical and engineering science for which England has become the centre and eye of the world.

The late Sir George Cornewall Lewis, in his valuable essay on the Government of Dependencies, enumerates six advantages, or supposed advantages, which nations have thought they derived from colonies, viz. :—

- 1st. Tribute and revenue paid by the dependency.
- 2nd. Assistance for military or naval purposes furnished by the dependency.
- 3rd. Advantages from its trade with a dependency in the sense of a monopoly of special privileges.
- 4th. Facilities afforded by dependencies for the emigration of its surplus population, and an advantageous employment of its capital.
- 5th. Transportation of convicts to a dependency.
- 6th. Glory.

It will be seen from my preceding remarks that scarcely any of these are now of great importance to England as the dominant country. If any, her benefits are of a moral and intellectual character. I have named the extent of land, similarity of laws, sphere for the cultivation of theoretical and practical science, but I cannot pass over another advantage, as I regard it—I refer to the variety and quality of the openings for the studying and learning the art of government which our numerous colonies and dependencies present. Educated men from England depart from our shores to undertake the government or charge of millions of men scattered over all the earth, thousands of miles from the mother country—called to rule mixed races, to rely upon themselves, to raise armies if need be, to work upon, to countenance, to conciliate conflicting interests and passions; as dictators to decide for themselves on the moment, and with only the salutary moral fear of a distant English public opinion to check or control them beyond the high tone of their own character. And in this respect our colonies afford a magnificent school, highly beneficial to the colonies or dependencies, the mother country, and the world. Do we not all feel a tingle of proud satisfaction that men of the stamp of Hastings, Clive, Wellesley, Metcalfe, Elgin, Canning, and Lawrence should govern large portions of the human race, and that they are our countrymen, in many cases sprung from the ranks by the

native energy of their surpassing talents, which have raised them to the highest positions of fame and usefulness.

DISADVANTAGES OF COLONIES TO THE HOME COUNTRY.

The advantages we have named are not without drawbacks. Philosophers tell us that the effect of natural forces diminishes in far greater ratio than the mere distance from the centre of power, and history records that as nations or conquerors have attempted to rule over or conquer remote provinces the hold has ever been loose, difficult, transitory, and failing, generally felt to be oppressive by the province, always exhaustive of men and money to the dominant state. And wherever the governing power has either attempted to compel the inhabitants to render military service or to contribute by taxation to the needs of the central authority, the result has been the same, whether under Greek, Roman, Spanish, or English rule. Confining our thoughts to a slight survey of our own English position, we may observe that our army being small and derived from voluntary enlistment, the necessity of garrisoning so many colonies places us at a great disadvantage in carrying on any considerable military operations by land, whether at home or abroad. Had the whole English army been available for the Crimean war our national position in that affair would have been altogether different, both as regards allies and foes. Were the islands of Great Britain the only coasts we have to guard, our fleet would be amply sufficient, when at its least effective strength, to render us safe from attack; but the fleet, like the army, is scattered in detached fragments the world around—a frigate here—a liner there—thousands of miles apart. Not only do we suffer from the available force at home being so crippled in numbers, but the retention of colonies requires both our army and navy to be much more numerous and, therefore, more costly than if we had the home country only to defend, and this great expense (it, perhaps, would not be too much to say half the total) falls heavily on the English taxpayer. Our colonies present our most vulnerable point to an enemy, the attack can be concentrated upon any one spot, whereas the means of defence are widely scattered. Can anyone doubt for a moment that the unseemly language and overbearing conduct of the United States of America during so many years past have been entirely owing, not to any real cause of offence given by the people or the government of this country, but to the fact that we have one vulnerable place in the event of war with the Federal States. We should have the almost impossible task of defending a land frontier of twelve hundred miles in length which could be crossed at any spot by an invading army. Combinations of other naval powers could pounce upon some of our colonies and temporarily occupy and cause great distress to, if not permanently possess them, but in the case of Canada no sea voyage is necessary, we are exposed to the attacks of an ambitious people, now possessing a large army, the reabsorption of which into the ordinary occupations of life will require all the judgment of the governing powers.

It may be said that the Imperial Government can, by moderation, wisdom, and uprightness, prevent such a result, or at least so control its conduct, that, whatever may ensue, it will stand justified in the sight of the world. The danger, and the vast expense it causes, nevertheless exist, and Canada is a continual anxiety.

Thus far with reference to the danger we incur from other nations and governments on account of our colonies. In many cases, however, the home country has to bear the burden, wholly or in part, of local wars to which she has no inclination—wars entered into without her consent, contrary to her advice, and for purely local reasons and advantages, and out of which England—as England—can derive neither benefit nor honour. I refer to such wars as many of those we have had in India, at the Cape, and, at the present moment, in New Zealand. One or two sentences in reference to the last will put this subject in a clear light. That question has three

aspects:—1st. The Imperial. 2nd. The Colonial. 3rd. The Native.

Before New Zealand became a colony, the Imperial Government entered into an arrangement with the natives, one item of which arrangement was that the natives should be allowed to keep their land if they chose, and neither be compelled to part with it by sale nor have it taken away. The Colonial Government cannot cancel the obligations of that treaty, whether wisely or unwisely made, but years subsequently to the arrangement, and after a constitution had been granted to the European part of the community, the anxiety to obtain land for speculative purposes (it cannot be for present settlement, because no one will contend that the land now owned by Europeans is brought under cultivation to anything like its full extent), caused the Colonial Government to purchase land from a chief who was not the rightful owner. When possession was refused, instead of pausing and inquiring into the merits of the case, a course suggested to the Local Government, by the Bishop and the Chief Justice on the spot, and by myself in England to the late Duke of Newcastle, the *wrong man's title* was supported by an armed force, and this I consider to have been the primary cause of the present war. After the arrival of the new Governor, the question of the title was investigated and the land *given up*, but bitter feelings had arisen, revenge and all the bad passions which murder, robbery, and burning create, had by this time taken deep root and extended. And England has had to pay some millions of money for a war incurred chiefly about this miserable squabble respecting 600 acres of land.

I name this one case to show our liability to incur enormous expense for the sake of our colonies. However right or wrong they may be, we must stand by them even in their local wars. The Colonial Government may say, "Let us alone and we will settle our own local difficulties," but they should also recollect that the Home Government cannot always allow such license, its own word and arrangements have some claim to be upheld, and in the present instance the local government was not in existence when the bargain was made; the arrangement was made direct with the Queen's representative, and the government of the natives has always been excluded from colonial control.

Again, at one period, when this country could send its convicts almost whithersoever it preferred, when our home manufacturers were highly favoured against foreign productions, when we had the monopoly of colonial shipping and carrying trade—selfishness might have induced us to retain our colonies with a pertinacity comparable to the vigour with which we had obtained them. But now, when they are placed upon the same basis as ourselves, in reference to trade; when perfect freedom exists in all or nearly all of our colonies; nay, when some of them are contemplating and even enacting protective duties against the home country, I must boldly say that our liabilities on their account are so great, that whenever any one of our colonies, or all, are disposed to separate from the mother country, and are no longer desirous of sheltering themselves under the parental roof, but, like grown up sons and daughters, are ambitious to settle for themselves, I should cheerfully assent, wishing them all success and God-speed.

SEPARATION FROM THE MOTHER COUNTRY.

This brings me to inquire whether the colonists themselves desire to withdraw from the government of the home country? I believe they all desire to retain their connection with the home country. However free and unbecoming may be the language of some of the colonies towards the home government, occasionally amounting almost to insolence, yet looking at the matter broadly and over a lengthened period, it must be unhesitatingly asserted that there is not at the present moment a single colony at all desirous of throwing off allegiance to the home country. Two or three reasons, out

of many which might be given for this satisfaction, may be named. First, for the most part the colonists have had large and liberal constitutions granted to them, whereby each colony is empowered to make its own laws, raise its revenue in the form most agreeable to itself, an act which it sometimes does very much to the prejudice of the home country—in fact, with few exceptions, to govern itself as independently as if it were a distinct nation. Not only so, but they possess the additional advantage of bearing but a comparatively small share of the cost of their own defence, and have the most powerful maritime nation in the world committed to their protection. And it is scarcely too much to assert that if the flag of England were hauled down and ceased to wave over our colonial possessions, the smaller ones would most certainly, and the larger ones very probably, soon fall a prey to less lenient control than the British. Again, consider the rate at which the several colonies borrow money for their local improvements. The direct monetary advantage of the guarantee of the home government is very considerable, or it would not be so eagerly sought. Even without that, a British colony comes into the money market with confidence, and secures loans on terms which most foreign countries would be extremely glad to obtain.

There is another matter, which the better class of colonists deem of great importance in a social point of view. If detached from the old country they would probably, almost necessarily, form republics, and have all the burning heats of violent political partisanship, presidential elections, &c., and take their whole tone of society from the narrow limits of a small population, the key-note of public feeling, sentiment, and manners being struck from the uneducated mass, working from below, if I may so speak, upwards. Quite apart from all questions of dependence and monetary and material advantages or disadvantages of a connection with the mother country, the best class of colonists value this connection for reasons which may be thus stated:—Nominated by her Majesty, who is too elevated by her position to have any other motive than the welfare of the colonial community, the authority of her appointed governor unembarrassed by local ties or influences, fresh to the colony, and generally a man of superior education and knowledge of the world, accompanied by an accomplished wife, a lady by manners and birth; the prestige of a bishop and clergy carrying to a greater or less extent profound respect for the learning of Oxford and Cambridge to the uttermost corners of the earth; the presence of military officers, the mild excitement of the inspection of the few troops stationed in most of the colonies, the periodical playing of the military bands, enlivening the otherwise dull business existence and softening the rude competition of the majority of the settlers—all these the colonists feel tend to raise the tone and give an old-home air to colonial society. Again, the visits of our men-of-war are always looked forward to with pleasure, even the solemn magisterial office regarding the escapades of Jack ashore with a very lenient eye; and the youngest and most mischievous midddy who can display her Majesty's button may safely reckon upon finding a hearty welcome in every settler's home, whether the veriest log-hut or of palatial pretensions. Many military and naval officers form such associations and attachments in the colonies in which they may have been temporarily located that they eventually retire from active service and become settlers; and so much are they desired as colonists that special advantages are generally offered to settlers who may have belonged to her Majesty's service. Now, all must admit that the presence of a small court, if we may so term it, comprised of the elements we have named, is very advantageous to a colony; and I venture to assert that this class of advantages, more than the pecuniary benefits arising from the presence of government, induce those violent contests for the honour of being the capital, which we see exhibited in every colony. Witness the dispute as to whether Montreal, Toronto, or Ottawa should be the capital of

Canada, and the pertinacity with which the rival claims of Auckland, Wellington, Nelson, and Marlborough have been put forward for the honour of being the capital of New Zealand; the same may be said of Calcutta, which otherwise would certainly not long remain at the present day the capital of India.

CONFEDERATION.

I now venture to offer a few remarks on a subject which is becoming important, inasmuch as the results of the discussion now going on will affect, for good or evil, large territories of the globe, and millions of its inhabitants, of English blood, speaking our language, and retaining more or less the habits and love of the old country, and in whose destinies we cannot but feel a great interest. Colonies are first formed by a small settlement being made on the coast of some newly-discovered island or continent, and distance from the mother country necessitates the speedy establishment of a government, if such has not been previously arranged before the departure of the colonists. As the straggling colonists, with their innate love of wandering, proceed further and further from the primary settlement, often leaving large unoccupied gaps between the settled districts, it becomes advisable to have a second and a third focus of government, in order to bring these scattered populations under control. Hence boundaries, separate governors, legislatures, and revenue laws, applicable to the peculiar needs of each community. In process of time these communities, becoming more numerous, approach and touch each other, and that which formerly was a necessity for separate colonial legislation becomes incidentally followed by inconveniences. Local jurisdiction, difference of revenue duties, weaknesses from dissension, all occasion difficulties and disputes. From this cause, and more particularly from the threatening language of the government of the Federal States of North America, this question of the federation of colonies, has recently been revived. Time does not permit us to discuss this matter largely, but it may suffice to point out a few of the main principles which should guide the establishment of a federation.

1st. Equitable adjustment of taxation and duties, internal and external, for revenue purposes, that there may be no inducements to smuggling and fraud, and the expense of frontier custom-houses, watchmen, or coast-guards may be rendered unnecessary.

2nd. One system of monetary regulations, currency, coinage, and banking laws.

3rd. Uniform criminal and commercial laws.

4th. General application of loans for public works, and combined naval and military defences.

The disadvantages of confederation of this kind are to be found in the comparatively greater attention which would be given to general, rather than to the individual or local interests of the separate districts or provinces, and the subordination of the local governments to the central authority, the consequent diminished importance of the provincial councils and capitals, the swallowing up of the local in the central, and the want of recognition of these peculiar advantages, which each small colony believes itself in a position to offer to the intending settler. On the other hand the advantages are manifold. All border disputes about taxation and revenue would entirely cease. Is it not absurd, for instance, that goods imported into South Australia should pay one rate of duty, and through Victoria another, and that the running of customable goods across the border of adjoining colonies should be a source of profit to the unscrupulous, attended at the same time with great expense to the colony more highly taxing any given article, in order, by customs' stations on the frontier line, to protect its revenue. Again, unseemly quarrels about postal service, as between Victoria and New South Wales, would be avoided or overruled, as the general government would not be likely to have local preferences. As each district, from its

geographical position, animal, vegetable, or mineral resources, necessarily varies in its peculiar requirements and the inducements it offers to emigrants, so it may be laid down that, subordinate to certain general principles and laws, which should include the fewest subjects possible, and be as clearly defined as practicable, the separate provinces or colonies should possess all the freedom of legislation and action compatible with the general good. It is evident that a fishing, a timber, a corn, and a sheep-farming colony may and must have very different modes of regarding the laws which should govern its taxation, its offers of land to emigrants, and the constituent elements of its general prosperity.

It would seem therefore that federation may more easily be longitudinal than latitudinal, climate having so much more influence on the welfare and social habits of human beings than at first sight we are apt to suppose. A tax upon wool, for instance, which would be oppressive at one extremity of a confederation, 1000 miles in length latitudinally, and almost unfelt at the other, might be an equally felt burthen in a confederation of 1000 miles length longitudinally. Whether this be a precisely correct view in every case or not, certain it is that, without permanent and close similarity of interest, confederation would be difficult, very probably not advisable. The excitement of a common danger is a very ephemeral bond; and the moment the fear of the threatened danger ceases, the chafing of the bond is inconveniently felt. In the last century the common cause of severing from England, united the several colonies of America, against the mother country; but the danger of the anticipated punishment for rebellion having ceased, the difference of internal interests is causing the most ferocious war on record.

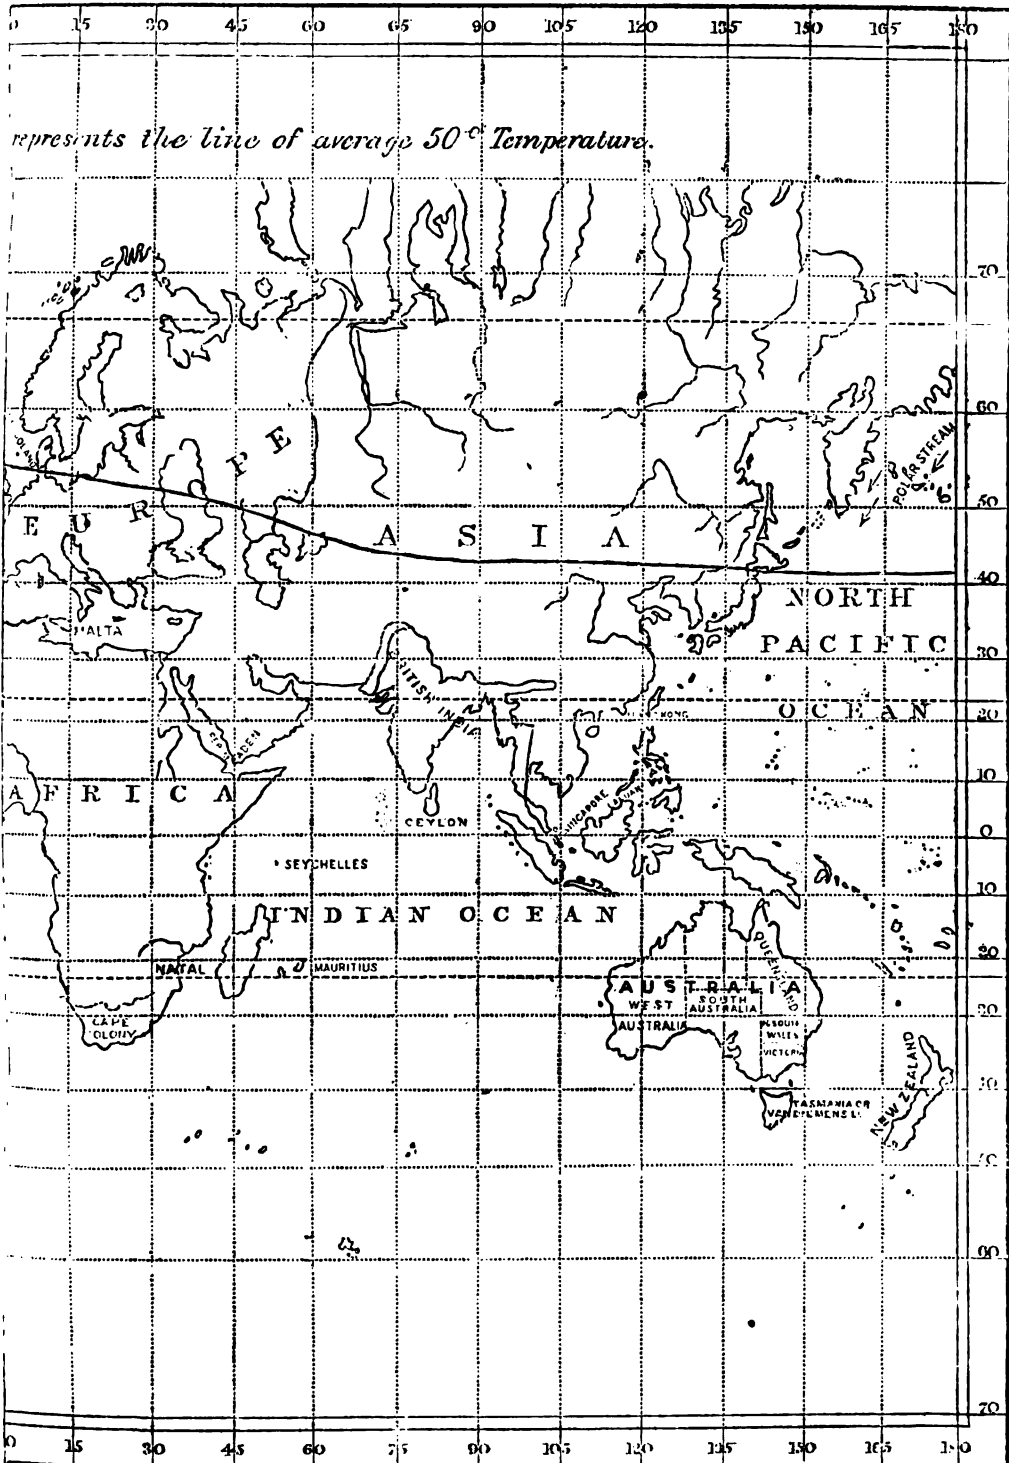

The confederation of several colonies for purposes of defence in case of invasion is doubtless very desirable. Conquest is not the result of an invading force being able suddenly and momentarily to overrun a country, for however disastrous to the peaceful inhabitants such a visitation always is, this curse may be only temporary, and the marauding wave be eventually driven back. It is most important for security against such inroads, to check their progress if attempted, or to recover lost ground, that strong positions, either presented by natural advantages of situation, or arising from scientific constructions, should be judiciously selected, capable of offering stubborn resistance to the invader, and regarded as barriers or nuclei, behind and into which the militia, volunteers, and small military force of the mother country, to which every colony at the outbreak of war must necessarily be limited, may resort, and there make a resolute and permanent stand until their compatriots may have time to rally, and adequate assistance be rendered by the old country. In other cases these defences would probably consist of gunboats, dykes, moats, and canals, water impediments to the enemy. Plans of this kind can evidently be more advantageously and successfully carried out, the larger the population contributing such mutual assistance, and the greater the area for selection of good defence points. The rallying forts or entrenched camps would be comparatively fewer, but much stronger and more imposing to the invader than if each colony, island, or province had to rely upon itself unaided; and the naval and military combinations would be more effective and likely to secure the general result—the common defence. In this sense the union of several colonies is much to be encouraged. I do not at all agree with the idea that because Canada is not a desirable seat of war for England, therefore no attempt should be made at defence. Our being at a disadvantage there is a circumstance we cannot avoid, and must accept as we find. We should, of course, not select it as our field of battle, but when we know it is our weakest place, of which the enemy would be sure to avail himself, I read neither English history nor the national characteristics aright if I could believe for one moment that we would expose some three or four millions of our fellow subjects to the tender mercies of an army under such

SKETCH MAP, SHOWING THE COLONIES

It will be observed that the West Coasts of both Europe and North America are warmer than the East Coasts, and latitude of their position. The average temper. ... of London is about the same as that of Philadelphia, which

AND DEPENDENCIES OF GREAT BRITAIN.

also that the British Islands, British Columbia, and Vancouver's Island, are much warmer than is due to the mere is 14° further south; and the St. Lawrence, which is south of the Thames, is frozen over several months every year.

a man as Butler, without aiding them to make the best attempt at local resistance possible under the circumstances.

The question of colonial defence appears to be composed of three elements—mode of defence—expense—men. It would seem that the particular mode of defence in any given case must be left to the professional scientific advisers of the Crown and the colonies, with the understanding that the object is not for an English army or navy so much as for the local force. The expense of the permanent works in any given case should be borne by the colony, as it would be incurred for its special benefit, and the money would be spent among its population; but as any war to which the colonies might be exposed might be caused by imperial considerations, there would be little objection to the home government guaranteeing the interest. As the armament could be better provided, so that expense might be borne, by the home government, which would have control over its disposal and removal. Colonists should recollect that England is safe from attack; that we incur large expenses both of money and time on their behalf; money in taxes for the support of an army and navy principally employed in their defence, and time in large numbers of our people learning drill and the duties of soldiers, that we may allow our regular troops to be distributed all over the world. As to the men, no binding rule can be laid down; the number of the imperial forces must depend at all times upon its other needs; as a general principle the home force permanently located in any one colony could only be very small. Our colonies have been freed from control; their legislation is seldom advantageous, often adverse, to the mother country, and they must learn to bear the pecuniary burden of their own local defence.

CONCLUSION.

Upon the great empire which is presided over by our sovereign lady Queen Victoria, the sun ever shines; and as the morning gun boometh in a thousand ports, our pleasant red ensign floats on in the bright sunlight, greeted with a home thrill which only the emigrant exile can feel, for under its protection thought, speech, and action are free as the breathing wind which flutters through its wavy folds. At its sight ever the morning prayer or evening blessing wellets up in the hearts of English men and women, encircling the earth in one bond of union, freedom, and progress, for after the longest lapse of years, the look is still to Old England as their home. Shall the freedom we enjoy, and which, by our colonial empire, is spreading throughout the world, be curtailed and shorn of its proportions, or shall we, faithful to our high trust, diffuse throughout the world the liberty which our forefathers died to achieve, and with our privilege accept its responsibilities? We think our countrymen will give but one emphatic answer to the question; and while our colonial brothers desire to remain under the mild rule of our widowed Queen, they will ever find their English friends willing to stand with them shoulder to shoulder on their behalf, ready for quiet victory or silent death.

DISCUSSION.

The CHAIRMAN, before inviting discussion on this interesting and important subject, would make a few observations upon the singularly valuable paper which they had just heard. Mr. Stones had observed that he had purposely abstained from saying anything about ancient colonization; but, from the very able character of the paper throughout, he (the Chairman) could have wished that subject had been treated of, because it was one of the most interesting in the world. All we have in taste, in art, in beauty, in poetry, and in philosophy, came from the Greek colonies, which had led to the foundation of Rome. This subject was peculiarly interesting to ourselves, inasmuch as it would seem to have been our mission to conquer the dusky nations of the east, and to people the lands of the fertile south with a race of hardy

islanders. He, therefore, quite agreed with the sentiments expressed by Mr. Stones with regard to emigration, of which it might truly be said that "it blesteth him that gives and him that takes." A farmer in Wiltshire had lately stated to him that he remembered the time when the labourer considered himself well paid with the price of a bushel of wheat for his wages; he was now paid the price of two bushels, thus showing the effects of emigration upon the welfare of those who remained at home. He quite agreed that emigrants should be men who could do hard work—professional men were not so much wanted. With regard to the supply of raw materials from our colonies, he could only say this—that in the late dearth of cotton we had searched the world through for supplies of that material. The magnificent empire of the Brazils; the south of China, containing the most industrious population in the world; the valleys of the Tigris and Euphrates had together given us but little; but from our old dependency of India we had obtained about four-fifths of our recent supply. This showed how important an influence British rule exercised in promoting the supply of such raw materials as we required. He differed from the author of the paper in his idea that mechanical contrivances would have the effect of making labour cheaper. He saw before him an honourable friend (Mr. Bazley) who had a great deal to do with mechanical contrivances, and he was sure he would confirm the statement that the more mechanical contrivances thrived the more they tended to make labour dear. With machinery a man worked with the fingers of a giant, and was consequently better paid than if he did the work with his own hands, as the production was so much greater. In fact, mechanical contrivances ultimately tended to raise wages. With regard to the danger of foreign attack upon our distant colonies, no doubt that danger was increased in proportion to the spread of civilization over the world. It was thus rendered necessary for the mother country to maintain enormous armaments and fleets for the protection of the interests of her colonies, but these also afforded us the means of making effective reprisals in case of an attack on any of our dependencies. If the French were to assail our West Indian colonies we could bombard Brest, or some other seaport, in return; therefore it was not probable they would do this, because the retribution would be greater than any injury they could inflict upon our distant colonies. There were in the paper some very striking remarks with respect to the extraordinary feeling of brotherhood produced by political and commercial connection. It would seem that in the present day, when the principles of free-trade prevailed, there would be no advantage in this political connection, but the contrary was the fact. Take for instance the Cape of Good Hope, which was perhaps rather an ill-favoured colony. We gave up Java and Sumatra to the Dutch and kept the Cape, and it was a remarkable fact that our exports to the Cape were now five times what they were to Java and Sumatra. No doubt if the political connection of this country with those islands had been maintained, the exports would have been much larger. Take again the instance of the Mauritius—a beautiful little island, not larger than the Isle of Wight. The exports from this country to that small colony were more than ten times as extensive as those to the great country of Mexico; three times as great as those to Moldavia and Wallachia; and twenty times as great as those to Persia. Then take India—the exports to that country were twenty millions annually, whereas to China, with a large population—more industrious though less frugal—the exports were only five millions. If we were in possession of China as we were of India, our exports to that country would probably amount to one hundred millions per annum. These were some of the leading advantages of our colonial possessions. The paper referred to another subject of importance—that was the granting of free institutions to our

colonies. He was afraid that in that we had been somewhat precipitate. It was done no doubt with the best intentions, but it had launched some of those infant communities into the wildest democracy the world had ever seen, and had given rise to forms of government which the most advanced liberal would tremble to see introduced into the old country. He agreed with what Mr. Stones had said on the subject of transportation. It was impossible, in the present state of society, to keep people immured in gaols for any very lengthened periods. Imprisonment for life, or even for ten or fifteen years, was endurable to the worst of criminals, and transportation somewhere appeared to be desirable upon all considerations. He had seen the working of the system in the Australian colonies, and he could assure them that under the old plan, which was after all not particularly well carried out, the best results were produced. The Falkland Islands had been suggested as a locality for the transportation of criminals, and in that suggestion he concurred. It was a very windy place, where it was said "the hair was blown off one's head," but perhaps that was a climatic condition good enough for convicts. With regard to confederation, however desirable that might be, there were difficulties in the way of it, though not perhaps insuperable. We lived in times when we had seen the great American Confederation broken up; they never could be friends again, whatever happened; and this showed that in any confederation of the Canadas and other colonies there would be great difficulties. With regard to what had been said as to the cost of maintaining the naval protection of our colonies, they must remember that our navy required arsenals all over the world; and these must be furnished whether we had colonies or not. It must not be forgotten that our commerce every year amounted to nearly six hundred millions, including the carrying trade. The maintenance of our navy cost ten millions per annum, and if it were for nothing else than for the protection of our commerce on the seas this would be but a small per-centage upon the whole.

Professor LEONE LEVI said—Proud as this country might be in having given birth to so many communities, some of which had already become incipient empires, proud as she might be in possessing a territory so vast, a population so extensive, and resources so great as had been so vividly described this evening, there were causes in operation which were likely to lessen materially the need of possessing such colonies, and which would render the possible separation of any of them a matter of much less solicitude than would have been imagined some years ago. What were the principal benefits supposed to be derived from the colonial system? Practically three only: a large field for emigration; an extension of trade, with facilities for the investment of capital; and political strength and influence. Much was said of the field afforded by colonies for emigration. He could well conceive that in times gone by, when countries knew each other only by their armed forces, when there was no protection beyond what could be obtained by the national flag and national power, it became necessary for our redundant population to found colonies where they might establish themselves in safety. When war was the normal state of international relations no one could risk himself in the dominions of other countries. But the times were now, happily, quite changed in this respect. Now that peace was the rule and war only the exception; now that international law and public law reign supreme everywhere, there was no longer the necessity of seeking the shield of British protection within the national territory. Our emigrants were, in fact, but little affected by such national considerations. Take the emigrants for 1862 to the United States and British North America. One was foreign, the other British. Yet 59,000 went to the one and only 15,000 to the other. No doubt a common language, common laws, common manners, would always

be important considerations for an emigrant in the choice of a country, but even those elements were now greatly modified by the constant merging of nationalities, by the greater assimilation of manners, the better knowledge of languages, and the greater charity which obtained everywhere for the foreigner. Secondly, as to commerce it was admitted that a third of our entire trade was now carried on with the colonies, and that more than half of the entire trade of the colonies was carried on with the United Kingdom. This showed that as the colonies were of great importance to the United Kingdom, so the United Kingdom was of the greatest importance to the colonies, but that did not depend on the present relation of the colonies to the mother country. It only evidenced, on the one hand, the capacity of these territories to produce articles of great and universal value, and on the other, the capacity of the United Kingdom, as the largest market of the world, to attract such produce to its shores. In the present state of our colonial legislation the colonies were no longer bound to send their produce to this country. They sent it because they got here the highest price for it. They sent it because they were sure of a market. They sent it because they were greatly indebted to this country for the manufactures they purchased and for the capital Britain invested in them. He admitted the fact that such colonies were of great value to our trade, that they supplied us with articles absolutely necessary for our consumption and for our manufactures, that they consumed a large amount of British goods, greater of course than other communities; but he doubted whether this was because they were our colonies. It was simply because they followed the natural laws of trade. As for the investment of capital, he had yet to learn what guarantees were afforded in any of our colonies greater than were obtainable in other countries. The advantage they possessed was that they had virgin soil to work upon and infant communities offering the most brilliant prospects of increase. But that resulted from circumstances natural to the territories themselves, their soil, their climate, and their power of production. The third prominent advantage which colonies seemed to confer was strength. But, ignorant as he was of the art of war, he certainly scarcely thought that, in a strategic point of view, our colonies were not of any great value, at least the greater number of them. They were rather calculated to scatter our forces, to divert our attention, and to weaken our power of offence and defence on the high seas, where, after all, the great conflict of nations was decided. He would not enlarge on this point, since persons of greater practical knowledge might be ready to disprove any such consideration. Yet it was a question of importance to consider whether our colonies were really imparting strength to the empire or not. Time, indeed, was when the extension of territory was considered a primary condition of political influence, but we know now that the larger the territory the more difficult it was to govern. Look at Russia, how hard it was for the central government effectually to rule the extremities. And what did we experience ourselves? Could we govern India from this country? Could we govern Australia? It would be morally impossible. Most of our colonies were, in fact, self-governed; in some all authority was left in the hands of the governor, legislating alone or with a consultative council; in some the power was in the hands of the legislative council, partly nominated and partly elected; and in other cases the authority was entrusted to an elective council and an elective assembly; but in each case very little power was vested either in the Secretary of State or in the Queen herself. There was, no doubt, much glory in the name of possessing countries so great, but as to any attempt to direct the government of them, it must be renounced altogether. If, therefore, no great practical advantages arose from the present bond of colonial relationship, we might be quite sure that the time would soon come when questions of separation would force themselves on our attention, whether they were pro-

voked by the colonies themselves, or by thoughts of rigid economy, or otherwise. An evidence of the altered state of public opinion on this subject was given in the cession of the Ionian Islands. Some twenty years ago it would have appeared sheer madness to have parted with such colonies in an important position in the Mediterranean. Now they were abandoned without a sigh. It would, perhaps, be said that this was only another manifestation of the grovelling spirit of the age, but, in truth, it was the result of a great change in the prevailing opinion as to the real sources of national strength and prosperity. What would further facilitate this impending separation, would be the confederations now negotiated. It would never be possible to abandon these infant communities to themselves so long as they were isolated, but let them associate themselves into great federations, and they would be able to stand their ground, and to place themselves firmly under the protection of public and international law. What we should do was to render these federations as complete as possible; and he was glad to find in Mr. Stones' paper some valuable suggestions in this respect. What they certainly should aim at was an equitable adjustment of taxation and duties founded on the dictates of economic science. It was a disgrace that any of them should resort to protective export duties after the mother country had taught them better things. If any country should be able to experiment on the working of a complete free-trade system, it should be our colonies with their small expenditure and their thriving population. They certainly should have one system of monetary regulations, currency, coinage, and banking laws, and they should have a uniform criminal and commercial law. We were lamenting the differences between the laws of Scotland and England. But what were these differences to those arising from a completely different system, some colonies having Dutch, some French, and some Spanish laws, setting aside India with its Hindoo, Mahometan, and Parsee laws. These were practical difficulties which we should endeavour to remove. It certainly appeared that some of our colonies, such as Canada and Australia, had reached the state of manhood; and it depended very much on themselves to determine what kind of relation they would continue to hold with the mother country. Britain had certainly fostered them in their infancy, and watched their growth with all the solicitude of a parent, and should they now desire to part, it would become her duty to regard them, not with jealousy, but with sympathy, and to act towards them, if not with patronage and fatherly interest, at least with brotherly affection and brotherly encouragement.

Mr. TORRENS said, while he agreed with all that had been said in the paper with regard to the advantages derived by the mother country and by the colonies from mutual connection and from emigration, he entirely dissented from what had been said with respect to the counter-balancing disadvantages of that connection. He had the best opportunities of forming sound opinions on this subject, having early in life emigrated to a new country, now highly prosperous. He referred to South Australia, where he had filled the office of Commissioner of Trade and Customs. He joined issue with the author of the paper on the statement that our colonies were exhaustive to the mother country in men and money. On that point he thought the paper answered itself, because, in the early part of it, Mr. Stones dwelt appropriately upon the great increase of the wealth of the mother country, occasioned by the demand for her productions by her sons transplanted into countries where they were more adequately rewarded for their labour. By that means they were enabled to consume a larger amount of British manufactures than if they had remained at home. It would be found that in the Australian colonies the average consumption of British manufactures throughout the entire population was £8 per head per annum. They knew that no labourer in this country consumed anything like that; but by sending a portion of the

surplus labour of the country to our colonies they enabled a larger population to subsist at home. Thus he maintained that colonization was not exhaustive to the mother country in men; far less was it exhaustive in money. If they looked around them in this great city they found those who had acquired wealth in the colonies spending that wealth in this city, besides which, there was the increased wealth derived by this country from the demand for our manufactures by the populations of the colonies. The next point alluded to as being regarded as a drawback was the cost of protecting the colonies, and that whilst that expense fell upon the mother country the colonists, in some cases, were at liberty to impose protective duties, so as to exclude the manufactures of the mother country. That was a state of things that ought not to exist; but while it did exist to some extent, it was well to inquire how it had arisen, and whether there was any necessity for its continuance. The mother country had hitherto generously and gratuitously afforded naval and military protection to the colonies, but they did not in many cases require it: and it was contrary to common sense that they should be exempt from the taxation which was borne by the people at home for this object. He maintained that this state of things had in some cases arisen from the neglect of the mother country to make proper demands on her colonies in this respect, which would not have been resisted if made. It had been stated by Sir Henry Young that he sent home a despatch to the Secretary of State proposing that the colony over which he was placed should pay half the cost of the military protection, but that despatch he never received any answer. In South Australia, whence he (Mr. Torrens) had recently come, they maintained a large volunteer corps; and in Victoria a vote of £20,000 had been passed for the supply of heavy artillery for that colony. He did not hesitate to say that the great majority of the colonies were prepared to take their fair share of these burdens upon themselves. With regard to protective duties against British manufactures, he thought that when constitutions were granted to them they ought to have been prohibited from imposing duties which had the effect of excluding the goods of the mother country from their markets. He believed the true remedy for this objectionable feature would be found—not in separation or federation—but in a closer union with the mother country. If, instead of treating the colonies as foreign states, we treated them as integral parts of the kingdom, the result would be different, and the productions of each country would be admitted to each without duty, to the mutual benefit of both; and under such a reciprocity the colonies might be fairly called upon to contribute to the support of the naval and military defence of the common country. If this were the case, however, the colonies might then claim to be represented in the British Parliament—not by the whole extent of their numbers, but in such a manner as that facts relating to the colonies might be laid before the House from a colonists' point of view. He believed that system to be a practical one, and that thus instead of the colonies being a source of weakness and exhaustion to the mother country, they would become her greatest strength and support.

Mr. J. CRAWFORD said they had listened for an hour to Mr. Stones' paper, and he thought they all felt that hour was too short, so interesting had they found it. It had never been his lot to listen to a more comprehensive "state" paper; it might be regarded as the production of a true statesman, and he was most heartily obliged to Mr. Stones for it. There were, however, a few points in which he differed from him. He had said that most of our raw materials—even cotton—were derived from our colonies. His friend, Mr. Bazley, knew very well that cotton had not been brought to any great extent from our colonies. Our great supply of that article had been derived from a country which certainly ninety years ago was a colony of this empire, but which since that time had

become a cotton-producing country. We had been receiving some inferior qualities of cotton from India; but when peace was restored in America this product would come from that country as before, because no spot in the world appeared to equal the Southern States of America for the production of a high quality of cotton. He had no objection to make with regard to wool. Our colonies certainly did furnish us with enormous quantities of wool, and the prosperity of this country greatly depended upon that product. He thought, in the statement made by Mr. Stones, in which he attributed the rise of 20 per cent. in the wages of labour in this country to emigration, sufficient allowance had not been made for the large importations of gold from our own colonies. This enormous influx of gold had been going on for the last sixteen or seventeen years, and thus, in fact, our capital had been largely increased, giving employment to so many new hands, and constituting an additional demand for labour. Therefore, to the introduction of gold he principally attributed the rise of wages to which Mr. Stones had referred. With respect to confederation, he pretty nearly agreed with Mr. Stones on that subject. He did not see that any particular advantages would result from it to the colonies themselves, except, perhaps, in the case of the Canadas. He did not believe they would ever get Australia or New Zealand to form a confederation, inasmuch as danger from a foreign enemy was of the very remotest kind as regarded those colonies. They were able to defend themselves without soldiers, with the assistance of the British navy. The only great maritime powers who could attack them were France or America, and neither country had a navy equal to our own. With the Canadas, however, the case was different, with its 1,200 miles of frontier, which it was impossible to defend; with Montreal not more than 50 or 60 miles from that frontier, quite indefensible. He did not see what advantages New Brunswick or Newfoundland could derive from a confederation with the Canadas. He would say generally when any colony desired to part from us, the sooner we got rid of it the better. The Canadas were no great advantage to us; but we were bound in honour to defend them so long as they looked to us to do so. He did not, however, think we could defend them with success against the powerful nation that was on their frontier, who, with a large disciplined array, might at any time invade Canada; but, in his opinion, they would not do so because it could only be done at the cost of a vast sum of money; and the interest on their national debt already exceeded our own. Moreover, if they went to war with us, every port they possessed would be blockaded by our ships. He had, in conclusion, a very few words to say in reply to the observations of the chairman with respect to the ancient colonies. They were, after all, but very small matters. Every country that possessed a few boats—and the Greek vessels were little better—every country that possessed islands was pretty certain to engage in maritime enterprise, and the Greeks had an extraordinary enterprise for so small a people; for their whole number did not exceed the population of Australia and New Zealand at this moment. But for the discovery of America there would have been but little land for colonization, and previous to this discovery certain other discoveries were made: paper, printing, the polarity of the magnet, and gunpowder. Then it was that a great amount of maritime enterprise was manifested. In ancient times it was true that the Greeks planted themselves among barbarous nations, but there was little scope for colonization in the old world, while the new world afforded an almost unlimited field; and as soon as European enterprise was ripe for the work the foundation was laid of the vast colonies now owning British rule.

Mr. THOS. BAZLEY, M.P., fully concurred in the general impression as to the very able character of the paper; it contained much of enlightened policy; at the same time he thought that the author had in one or two places spoken hardly of the people of the United States, and of

some of the leaders of the armies of the North. In this respect he begged to express the strongest dissent from him. Nor could he let pass, without a slight criticism, the remark which had fallen from his hon. friend in the chair, to the effect that the re-confederation of the States of America could not be looked for, and that it would be impossible to restore harmony between those States. He (Mr. Bazley) thought, seeing that victory had given to the North something like a restitution of territory, there was no occasion for that remark to have been made on this occasion, while we were uttering expressions of sympathy for the loss which the States had experienced through the murder of their President. The South had rebelled against the North; and the South had no moral claim to the sympathy of this great and free country, owing to the institution of slavery. The negro had been debased, but he was now receiving something like vindication in the punishment which was being inflicted upon the slave owners of the Southern States. We had given freedom to the slaves in the British West India Islands, and they were more productive under the state of freedom than they had been under the system of slavery. Touching the question of protection, there was the evidence of what we did for the West India Islands. When they were under the system of slavery we paid (owing to protective duties) an excess of price for sugar imported into this country exceeding the whole amount of manufactures we sent there. We then squandered £4,000,000 per annum in the form of protection to our West India Islands. As to the connection of this country with the colonies, he thought that so long as they could maintain that connection with us, by all means let them do so. They had our customs, language, and laws; he hoped also they had our common sympathies, and that they would feel it to be to their interest to remain in connection with us; but he was quite sure not a moment longer than they deemed it to their own interest would they hold to this connection, therefore we need not be under any great anxiety as to retaining them. As to the quantity of raw cotton supplied by the British possessions for the great trade of this country, he would only say, that in the year 1860, the last year in which the cotton manufacture of this country was working to the full extent of its power, 85 per cent. of the cotton used in this country was supplied by the States of America, 8 per cent. by Egypt, and 7 per cent. from British East and West India; and, he need not add, that the worst quality of all came from the East Indies. The high price of cotton in this country had had the effect of stimulating a supply from our dependencies; but the maximum quantity we had received from the East Indies during the cotton famine had been about one million of bags in the year. In 1860, the consumption of the cotton trade of the country was equal to 2½ millions of bags; therefore, instead of a large percentage of the consumption coming from India under the most favourable circumstances, we had had only as 1 million to 2½ millions. But about the time the American convulsion occurred, the quantity of cotton did not indicate the quantity which the machinery provided was capable of consuming; and he believed the augmentation of machinery in the large establishments would have led to a consumption of three millions of bags if it could have been supplied. Thus the maximum supply from the East Indies of inferior cotton had been equal to only one-third of the consumption; but the inferiority of that cotton was such that the moment we could obtain an increased amount of American, that moment would East Indian cotton cease to be used. Under these circumstances, there was no doubt that, unless the resources of the British colonies were developed so as to compete with the independent states of America and Egypt, we could not obtain large supplies of cotton from our possessions abroad. Nothing could be better than the wool of Australia, and without it he did not hesitate to say a large portion of the woollen trade could not exist in the West of England

or in Yorkshire. He wished to record the fact that Australia could supply cotton equal to any produced in the world. Whether it would be to the interest of Queensland, Victoria, or the other colonies of Australia, to supply it he was not prepared to say; but it was certainly one of the resources of our colonial empire yet to be developed. He thought our colonies must not continue to depend upon the naval and military establishments of the mother country for the continuance of the connection with them. It might be very agreeable to them to see the parade of military life mingling with every-day business in the colonies, but all this had hitherto been done at the cost of the people of England; and the time had arrived when the colonies must not only look to self-support, but also to self-defence.

Mr. FREDERICK HILL would only say a word or two on the important question of transportation. More than 200 years ago Bacon declared that it was a bad and an unholy thing to plant wicked men in distant climates, there to multiply in their depravity; and as far as his personal experience went, the information he had collected went to show this principle was correct. The colonies most interested in the question had in the most emphatic manner denounced transportation to their territories; therefore we must consider the question virtually settled, so far as existing colonies were concerned. He would call attention to the circumstance that, while on most branches of the subject Mr. Stones had presented them with an interesting array of facts, yet, on the subject of transportation he had only theorised. It had been incidentally stated that the substitution of lengthened terms of imprisonment for the punishment of transportation had been a failure. Everyone who knew what had been done in Ireland must admit it was a most eminent success. The result of most careful inquiry showed that the system in this country had only fallen into disrepute from the miserable manner in which it was administered. The system of lengthened imprisonment, which it was argued was impossible without producing madness, or other evils, had existed, and did exist still, in Germany and Switzerland without those evils arising. It was no part of a proper system of imprisonment to confine a fellow-creature within four narrow walls year after year. That was only the preliminary part of the punishment, but afterwards they were treated in a different way, and under good arrangements, there was no difficulty in making the criminals support themselves, and thus disposing of them without injury to ourselves or to any distant country. Mr. Stones had recommended the Falkland Islands as the *locale* for a future experiment in this direction. The locality most resembling that was Norfolk Island, and the depravity that existed there when it was an island full of convicts, and entirely without the element of free labour, was so fearful, that one shuddered at the contemplation of a repetition of such a state of things. He therefore sincerely hoped that no such experiment would be tried.

The CHAIRMAN said it was his pleasing duty to propose that the cordial thanks of the meeting be given to Mr. Stones, for what they must all regard as an unusually able paper. With reference to the remark that had fallen from Mr. Crawford, that our trade with the colonies ought to be of the character of a coasting trade, he might say that practically this was so. With only rare exceptions, there was nothing charged with duty coming from the colonies, which was not also liable to excise in this country. There was, in fact, the most perfect free trade. Whilst there was an import duty on coffee, which was a foreign produce, there was a duty also on chicory, which was of home growth. There was a duty on rum from the West Indies, but the same duty was charged on spirits manufactured in this country. The great superiority of the American cotton was to be attributed to three elements—the fine alluvial tracts of the Southern territories, European enterprise, and African muscle. Those, when combined, produced the wonderful

result of excellent cotton at 6d. to 8d. per lb. With regard to Australian cotton, he was afraid it was hopeless to think of it. He was satisfied that at the present price of labour there, cotton could not be produced under 6s. per lb. [Mr. BAZLEY assured the chairman he was mistaken. He had grown cotton in Australia, and knew differently.] With regard to transportation, he would say the Falkland Islands presented a much larger area than Norfolk Island, and under the system recommended by Mr. Stones they would be acting upon the old plan of convict colonisation. He did not despair of something being done in these islands.

The vote of thanks to Mr. Stones was then passed and acknowledged.

DUBLIN INTERNATIONAL EXHIBITION.

This Exhibition will be formally opened by His Royal Highness the Prince of Wales, on Tuesday next, the 9th inst., at two o'clock. The doors will be opened at eleven o'clock and closed at half-past one. The general arrangements throughout the building are rapidly progressing, and no fear need be entertained of the preparations for the opening not being complete in time.

WEST LONDON INDUSTRIAL EXHIBITION.

On Monday, the 1st inst., this exhibition was formally inaugurated in the Floral Hall, Covent Garden, by the Right Hon. W. F. COWPER, Chief Commissioner of Public Works, who took the chair at three p.m., being supported on the platform by the Archbishop of York; Mr. J. A. NICHOLAY, president of the committee; Sir J. V. SHELLEY, Bart., M.P.; Sir James Hamilton; Hon. F. BYNG; Harvey Lewis, Esq., M.P.; Peter Graham, Esq.; Sir Thomas Henry; and others. Letters had been received from the Earl of Derby, Lord Stanley, and Mr. Gladstone, regretting that they could not attend.

The National Anthem and the 100th Psalm were then sung, and the Archbishop offered up a prayer appropriate to the occasion. The "Hallelujah Chorus" was then sung, after which Mr. Edmund Phelps delivered the ode written for the occasion by G. Linneus Banks, Esq., entitled "Labour's Festival." Haydn's "The Heavens are telling" was then performed by the chorus; and

The CHAIRMAN delivered an address, in the course of which he said there was one point which made the present exhibition important. In it we were brought face to face with the man who did the work, and he earned his just meed of praise. There was in these days so much power in combined action, that there was some risk of the cause of individualism being overlooked. A skilful artisan, who had done good service to the firm employing him, often had reason to complain that his merits remained unknown, and, while his employers had the credit, the individual could not show what he was able to do. The hon. chairman went on to speak favourably of some of the objects in the exhibition. He then declared the exhibition open.

Sir JOHN SHELLEY, M.P., proposed a vote of thanks to the chairman, which was seconded by Mr. HARVEY LEWIS, M.P., put by Mr. J. A. NICHOLAY, and carried by acclamation.

Sir JAMES HAMILTON moved a vote of thanks to the President and the Working Committee, which was seconded by the Hon. F. BYNG, and passed unanimously.

Mr. MORRELL briefly replied, and the Coronation Anthem—"Zadok, the Priest,"—was sung, and an inaugural march was played.

Space has been granted for 1,087 exhibitors, representing almost every branch of industry, from the profession of sculptor and artist to the humble calling of the cooper-monger, and by far the larger portion of the exhibition consists of amateur contributions.

Amongst the articles exhibited are many which were shown in the Exhibition of 1862, at the Society of Arts, at the coachmakers' exhibition this year, and at the recent district exhibitions; but the majority are articles manufactured strictly within the locality contemplated by the undertaking, and which are now for the first time brought under the eye of the public.

A certificate has been obtained from the Privy Council entitling exhibitors to the protection afforded by the Industrial Exhibitions Act, passed this session.

WORKING MEN'S FLOWER SHOWS.

Following out the laudable endeavours of the Royal Horticultural Society at South Kensington to promote the cultivation of flower-growing in what has been aptly styled "window gardens," a few of the inhabitants of Baywater called a public meeting on Friday evening April 28th, to devise means for carrying out the Society's views among the working classes resident in the parishes of Paddington and Kensington. These parishes are, of course, divided into districts, and in some of these districts—far removed from human ken, so far as the stranger is concerned—resides a large number of the "sons of labour," consisting chiefly of men engaged in the mass of building operations going on all around the "royal" parish of Kensington. Opposite Palace-gardens, turning down a wretched-looking court, you find yourself *vis-à-vis* with squalid poverty in the notorious Jennings'-buildings—a "rookery" which is a foul blot upon the parish. Although at first one may be led to doubt if the inhabitants of these dismal hovels can ever be led to attempt window-gardening, if we think what has been done by the parish of Bloomsbury (in which is situated the notorious St. Giles's), we shall not find cause for despair. The question of its accomplishment is the thing to be considered. That it is fraught with difficulties we know, but when we consider the advantages accruing to the lower classes by inducing a love for flowers and a desire to cultivate them, the difficulties are in comparison trifling. A man who is fond of his garden is fond of his wife and children; a woman who tends her flowers with care is a woman of cleanly habits, and her room will be found tidy; she trains her children as she trains her flowers, with care and attention. Is it not, then, worth our while to make an effort to create and encourage window and house gardening among the poor. Socially and morally will they be benefited, and their improvement is not only their but our advantage. The audience at the meeting consisted principally of youths, members of the West London Youths' Institute, in the lecture-hall of which building the meeting was held. They were addressed by Mr. Bosanquet, who, in conjunction with the Rev. S. Hadden Parkes, has done so much to teach the working classes the science of home floriculture. Mr. Bosanquet gave a practical lesson in window gardening, and he was listened to with profound attention. He clearly showed the ease and the readiness with which geraniums, fuchsias, and annuals can be grown on window sills in any part of London. Mr. Broome, of the Temple-gardens, also gave some good practical hints, none of which were thrown away on his listeners. The advice given by one speaker (Mr. Sharp) is worth recording, as other gentlemen who may feel an interest in this movement may circulate it in their own parishes. He says, leave the matter to be worked out by the City missionaries and district visitors in each parish. They know the people; they have influence over them, and will be listened to. If this plan be followed out we believe the movement will be a successful one. Let but two or three families in a district show the first bright streaks of newly-grown flower at their windows, and it will stimulate a desire among their neighbours to compete for the prizes to be given by the Royal Horticultural Society in

July next, and thus lay the foundation for a Working Man's Annual Flower Show. M. S. M.

Fine Arts.

FLANDRIN EXHIBITION.—The collective exhibition of the pictures of the late Hippolyte Flandrin, in the new gallery of the Ecole des Beaux-Arts in Paris, has recently closed. It has attracted a very large number of visitors, and, on the whole, may be said to have proved a success. The fact of a large portion of the works being merely the sketches—in some cases, it is true, highly-finished drawings—instead of the works themselves, which are on the walls of the churches of Paris and other towns, dwarfed the collection as a whole, and the large works, such as the "Dante, conducted by Virgil, offering Consolation to the Shades of the Envious," "Euripides writing his Tragedies," "Saint Clair," "Jesus and the Children," were not of a sufficiently brilliant character to fill the void occasioned by the above circumstances. Of the sketches for the innumerable works executed by this artist, including those for the churches of Saint Séverin, Saint Vincent de Paul, and Saint Germain des Prés, in Paris, and Saint Paul, at Nîmes, it is impossible to speak too highly with respect to drawing and industry; but, unfortunately, the composition is generally bald, even for mural painting, the attitudes wanting in originality, the colours flat, and the expression of the faces generally conventional, and wanting in enthusiasm. Passing, however, from the highest walks of the art to that in which Flandrin was, after all, most at home, the portraits deservedly draw forth a large amount of admiration. It is true that the charm of colour is almost entirely wanting. As Ary Scheffer performed strokes of genius in hues of dead leaves, so Flandrin has done miracles with black and plainness; he rarely succeeded in making a face pleasing, never in making one lovely, but the fidelity and life-like character of his portraits are marvellous. Amongst the pictures from the life, that of the present Emperor Napoleon III. is beyond question one of the most striking. The portrait of Prince Napoleon looked sombre beside its glaring companions—the likeness of Louis Napoleon and another of Napoleon I.—but its qualities are sound and real, and it is one of the works on which Flandrin's fame will rest. There is also a likeness of Baron James Rothschild, which is admirable in almost all respects. The gem of the collection, however, is the famous "Young Girl with the Pink," which created such a sensation in 1859, a likeness of Mademoiselle Maison, now La Baronne de Mackau. The face is an exquisite specimen of solid, vigorous, highly-finished work; the pose is perfectly natural, the dress is truth itself—there is nothing wanting but that indefinite charm which cannot be explained, but the absence of which leaves a vacuum that nothing can fill.

MONUMENT TO RAPHAEL.—The eldest son of Victor Emmanuel has performed a graceful act in accepting the honorary presidency of a committee formed for the purpose of erecting a monument in honour of this great artist in the city of his birth, Urbino, and the acceptance is announced in a note, in which General Revel says for Prince Humbert:—"To perpetuate the memory of men who, like the illustrious painter, have exhibited their genius in such brilliant colours, is a most praiseworthy act, and his Royal Highness could not fail to associate himself with such a generous and patriotic intention."

Manufactures.

ANILINE DYES.—The colouring matters produced from aniline and analogous matters are all, with the exception

of the Fuchsine and Perkins's violet, insoluble in water, and many attempts have been made to substitute a less costly solvent for the alcohol hitherto employed. M. Gaultier de Claubry, a French chemist, has recently taken out a patent for a method of accomplishing this. He says that a great number of substances, such as gum, mucilage, almond and other soap, glucose, dextrine, the gelatinous portion of various feculæ, of lichens, and of fuci, render water a solvent of such colouring matter, but that the best and most economical results are to be obtained by means of decoctions of the bark known as Panama (*Quillaia saponaria*), or of the root of the Egyptian soap plant (*Gypsophila struthium*). The *Saponaria officinalis*, he adds, may be employed, but is less energetic in its action than the other two. The solutions are obtained by pouring the boiling liquors upon the colouring matter in powder, agitating, decanting, and, if the solution be not complete, repeating the process. The solutions thus obtained may be reduced to extracts by evaporation, but continued ebullition, especially if the water contain sulphate or carbonate of lime, may injure the colours. A better method, according to M. Gaultier de Claubry, is to triturate the powdered colouring matter with the extract of *Gypsophila struthium*, and then afterwards to add water by degrees, but, as the reds dissolve more readily than the blues, it is necessary afterwards to mix all the products together. The solutions obtained by means of the extracts above named are said to work readily with gum, dextrine, and albumen, separately or combined. The advantages claimed for the process by the patentees are economy, perfect unity of tints, which will not soil linen by contact, and suppression of inconvenience caused to the dyers by the use of alcohol or wood spirit. In connection with the latter it should be mentioned that the attempt to substitute it for alcohol has been defeated by the workmen, who have, in many instances, refused to use it on account of its effect on their health.

VEGETABLE FLANNEL.—A correspondent of the *Athenæum* writes:—Those of your readers who take an interest in the manufacture of vegetable flannel from the *Pinus silvestris* may like to have the additional information that since 1860 there are two establishments near Breslau, in one of which pine leaves are converted into wool, while in the other, for invalids, the waters used in the manufacture of pine wool are used as curative agents. The process for converting the pine needles into wool was discovered by Mr. Pannewitz. In the hospitals, penitentiaries, and barracks of Vienna and Breslau blankets made from that material are now exclusively used. One of their chief advantages is that no vermin will lodge in them. The material is also used as stuffing, closely resembles horse-hair, and is only one-third its cost. When spun and woven, the thread resembles that of hemp, and is made into jackets, spencers, drawers, and stockings, flannel and twill for shirts, coverlets, body and chest warmers, and knitting yarn. They keep the body warm without heating, and are very durable. The factories are lighted with gas made from the refuse of the above manufacture.

Commerce.

LAKE SUPERIOR COPPER.—The total copper product of Lake Superior in 1864, as per tables published in the *Mining Gazette and Miner*, is 8,561,999 tons, producing about 6,850 tons of ingot copper worth 6,850,000 dols., and from each district as follows:—Keweenaw District, 2,548 tons 808 lbs. shipped; Portage Lake District, 4,292 tons 1,691 lbs. produced; Ontonagon District, 1,722 tons 500 lbs. shipped; total, 8,561 tons 999 lbs. This amount would have been from 1,500 to 2,000 tons larger had it not been for a great falling off in the products of the Minnesota—the scarcity of labour in some of the districts, and its employment largely in opening new mines.

AMERICAN WHALE FISHERY.—The year 1864 has witnessed a further decline in the number of vessels employed in this business, and the number now thus employed is less than at any time within the last 25 years, being 276, with an aggregate of 79,692 tons. The greatest number within the above-named period employed in the whaling business was in 1846, which was 735, amounting to 233,189 tons. The present number of vessels, however, is as large as the business will warrant.

Colonies.

NEW SOUTH WALES FINANCE.—It appears that the actual deficit for the year 1863 and previous years amounted to £389,822 1s. 10d., and to meet this Government issued Treasury bills to the amount of £400,000. The deficit for the year 1864 may be estimated at £400,000, and is accounted for as follows:—Decline in the customs, £60,000; decline in land revenue, £102,000; taxation scheme not passed, £220,000; total, £382,000. The statistics of the Mint for 1863 show that the operations for the year consisted in the receipt and re-issue of 498,332 ounces of gold of the value of £1,908,526. Four-fifths of this gold was the produce of the colony, but some came from Victoria, some from New Zealand, and some from Queensland. The value of the coin issued was £1,584,750. The gold issued as bullion was only valued at £342,212. This shows that by far the greater portion of the gold sent to the Mint is re-demanded in the shape of coin, and that the demand is merely assayed bullion is small. This may be due partly to the fact that the charge for coinage and for assaying is the same, but perhaps mainly to the fact that the gold is shipped for India, and that it is more available there as coin than as bullion. The Mint revenue for the year was £23,602, of which £18,555 was due to the gold of the colony. The amount of coin and bullion in the colony at the close of the year was not more than £1,024,049, of which £962,426 was coin in the several banks. The amount of paper money in circulation at the end of the year was £824,347, or rather less than the value of the coin held.

THE NEW ZEALAND postal contract with the Panama, New Zealand, and Australian Royal Mail Company has been ratified by the New Zealand government modifications. The subsidy, it appears, is to be £90,000, or, if a speed of 10 knots be adopted, £110,000.

LABOUR IN QUEENSLAND.—The working classes have held a meeting on the subject of carrying out the eight hours system, which (as stated by the colonial journals) has been found to work satisfactorily in other colonies. There are few persons in the colony who do not approve of the movement, as, from the trying nature of the climate, it is physically impossible that any man can work for more than eight hours with credit to himself or with justice to his employer. The arrangement is one which rests almost entirely with the working classes to carry out, and, as they have before them the encouragement of success in other colonies, there is no doubt that they will obtain a public recognition of the desirability of enforcing the eight-hour system.

GOLD IN QUEENSLAND.—The northern diggers are sending down large quantities of gold from Peak Downs and other places. The reefs at Falgai are proving daily to be of increased value. It appears that the stone which is being found there is in many instances very rich, so much so that the holders of claims are asking very large sums of money for shares in them.

TASMANIAN REVENUE.—The total land revenue for the last quarter of 1864 was £21,810 1s. 4d., showing an increase of £9,820 6s. 9d. over the same period of 1863. The total customs for the quarter ended December, 1864, was £33,800 1s. 7d., and the total for the quarter ended

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MAY 17.—"On the Manufacture of Encaustic Tiles and Ceramic Ornamentation by Machinery." By ZERAH COLBURN, Esq.

MAY 24.—"On the Development of the Trade with India, and the Bombay International Exhibition of 1866." By J. FORBES WATSON, Esq., M.D.

CANTOR LECTURES.

The Third Course for the present Session, consisting of six Lectures, "On Some of the Most important Chemical Discoveries made within the last Two Years," by Dr. F. CRAIG CALVERT, F.R.S., F.C.S. (Corresponding Member of the Royal Academy of Turin; of the Société Industrielle de Mulhouse; of the Société Impériale de Pharmacie de Paris, &c.), will be concluded on Tuesday evening next, at Eight o'clock, as follows:—

MAY 16TH.—LECTURE 6.—On the Discoveries in the Chemistry of Metals and Alloys.

These Lectures are free to Members (without ticket), and every Member has the privilege of admitting ONE Friend to each Lecture.

Proceedings of the Society.

DWELLINGS FOR THE LABOURING CLASSES.

The Committee appointed by the Council to consider this subject* have made the following report:—

The consideration of the best means of improving the dwellings of the labouring classes has for some time engaged the attention of the Society of Arts. In February,

1860, Mr. Twining undertook to collect information, both financial and sanitary, with regard to the efforts then being made for providing improved dwellings in town and country. The result of his inquiry was a large and important collection of statistics, which are now deposited in his museum at Twickenham. In order to reduce the information thus collected into a shape which might be useful in future efforts of a similar nature, a special committee was appointed by the Council on the 4th of November, 1863. The report of this committee, which has been printed and circulated, was prepared by Mr. Rigby, with the assistance of Mr. Twining. It contains a concise account of the various blocks of dwellings and renovated houses for families and single men in the metropolis and suburban districts, under the management of societies established for improving the dwellings of the labouring classes, or of individuals interested in the same subject, together with a statement of the primary outlays, annual receipts and expenditure, and other particulars, of these various buildings, arranged in a convenient tabular form.

With a view of eliciting further information on this important subject, the Council invited the attendance of all those who were interested in the movement to a conference on the 26th May, 1864, and on the following day. A large number of those who had taken a leading part in providing better dwellings for the labouring classes, both in London and the country, attended the conference, and much interesting discussion took place. It was strongly urged upon the Council by this meeting to form a committee, for the purpose of taking the whole subject into consideration, and in particular for considering in what way the Legislature could promote the erection of proper and sufficient dwellings for those classes who are so much in need of them.

The Council accordingly, shortly before Christmas, 1864, issued an invitation to various persons, whose interest and experience in the subject were likely to render their advice valuable. The committee met for the first time on the 22nd December, 1864, and continued their sittings during the spring of this year.

At the first meeting of the committee it was unanimously resolved that it was not necessary to collect facts to establish the unfitness of the greater part of the dwellings of the labouring classes as habitations for respectable and well-conducted families, or to prove that the excessive overcrowding which now exists in such dwellings promotes crime and immorality, harbours disease, and materially lessens the effective power of the working-classes, by injuring their health and shortening the duration of their lives.

* See present Vol. of the *Journal*, p. 145.

Nor was it considered necessary to inquire into the effect produced by these badly-constructed, ill-ventilated dwellings on the poor-rates, or into the amount of discontent which the admitted want of proper dwellings creates in the minds of the working-classes. The committee also recognised the distinction which must be drawn between associations for providing improved dwellings by investments for the labouring classes, the capital for which is subscribed with the double object of obtaining a fair interest on the money advanced, and of elevating the social and moral condition of the working classes, and the regular investment in such buildings by builders who must obtain the ordinary commercial profit on capital used in business. In the first case, a dividend of 5 per cent., with an ample fund to provide for all contingencies might be considered sufficient, whilst in the other case a very much larger return would be required. Considering these facts as fully established, the Committee proceeded to inquire into—

(1.) The causes which appear to retard the erection of proper house accommodation, and the improvement of existing houses, for the working classes in town and country.

(2.) The operation of imperial and local taxation on such dwellings; and the expediency of relieving them from all or a portion of such taxation.

(3.) The effect of the law of settlement and removal of the poor upon such buildings in country districts.

(4.) The probable effect of extending the area of local taxation in town and country.

(5.) The operation of the laws relating to the transfer of real property in small plots, and the conveyance of chambers and *suities* of rooms.

(6.) The operation of the destruction of houses by railways and other local improvements.

(7.) The desirability of facilitating the conveyance of labourers to and from their work by railway.

(8.) Whether the provisions contained in the existing Acts of Parliament, for granting loans for the improvement of estates, might not be extended to the building of cottages, and if so under what special conditions.

(9.) Whether the provisions of the common lodging-house act, and other statutes relating to the public health might not be advantageously extended.

(10.) Whether there are any other means by which the legislature can promote the object in view.

It was at first proposed to divide the subjects between three sub-committees, according to their relation to town dwellings, country dwellings, and proposed legislation, but it was found in practice better to amalgamate the sub-committees, as the subjects referred to each sub-committee were so similar. The following gentlemen attended the meetings: Mr. W. Hawes (Chairman), The Hon. and Rev. S. Best, Mr. D. R. Blaine, Mr. C. B. P. Bosanquet, Mr. C. S. Barker, Mr. Edwin Chadwick, C.B., Mr. G. R. Burnell, Mr. H. Cole, C.B., The Right Hon. W. Cowper, M.P., Mr. J. B. Denton, Mr. J. Dillon, Mr. H. B. Farnall, Mr. P. Le Neve Foster (Secretary of the Society of Arts), Professor Fawcett, Mr. C. Gatiliff, Mr. G. Godwin, F.R.S., Dr. Greenhill, Mr. T. Hare, Mr. H. Harwood, Mr. E. T. Holland, Mr. C. Wren Hoekyns, Mr. H. Maynard, Mr. H. Pownall, Mr. S. Redgrave, Mr. B. Shaw, Dr. E. Smith, F.R.S., Mr. S. Teulon, Mr. T. Twining, Mr. G. H. Walker, Mr. Alderman Waterlow, Mr. G. F. Wilson, F.R.S., Mr. T. Winkworth, Mr. J. Young; and Mr. M. Ware, who acted as Secretary to the Committee.

Various resolutions were passed with respect to the questions considered by the committee, the recommendations of which are embodied in this report.

IMPROVED DWELLINGS FOR LABOURERS NOT REMUNERATIVE.

It was shown that labourers living in the metropolis and other large towns pay a larger proportion of their income for rent than any other class in the country, and even then are unable to obtain suitable accommoda-

tion. The immediate cause of this state of things, in places where the law of parish settlement does not cause an additional difficulty, is the fact that providing such dwellings for labourers has not been found commercially remunerative. The efforts of societies and benevolent individuals are every year becoming more extensive, and from the beginning have been appreciated by the industrious classes. They have already accomplished a great amount of good, and have set an example which, it is hoped, will be more extensively followed; but it will be long before the existing evils can be more than slightly mitigated by such means. At present the dwellings provided in this manner in the metropolis only accommodate about 7,000 persons, and the commercial results are not such as to encourage builders and capitalists to undertake the building or renovation of dwellings for labourers as an ordinary matter of business. It appears from the statistics collected by the Society of Arts, that rarely happens that such undertakings produce a higher dividend than 5 per cent. on the original outlay, and that in most cases the returns are smaller. This rate of interest may be expected to satisfy a large number of capitalists, who are willing to accept a moderate return upon capital when connected with such important philanthropic objects, but it can hardly be expected that dwellings will be provided in anything like sufficient numbers until they can be made to produce such a return as will compensate a builder for investing his capital in this kind of property, attended as it is with so much more risk and trouble than houses of a superior class.

The difficulty of remedying this state of things is aggravated by the fact that the wretched houses which too many of the labouring classes now inhabit are, in their present condition, highly remunerative to the landlords. Consequently such houses fetch a high price when brought into the market. They may be made to yield a good profit in the hands of those who care nothing for the moral and physical well-being of their tenants; but the expense of putting them into proper sanitary condition, and adapting them to the wants of respectable working-men, reduces the returns so much as to render the undertaking, in a commercial sense, unprofitable.

It may be here remarked that the reproach which has been sometimes brought against societies established for providing improved dwellings, that they consider only the wants of the higher class of labourers, is not now deserved. Several societies have now under their management both blocks of buildings and renovated cottages, in which the poorest labourers are accommodated in single rooms at weekly rents of 1s. 3d. to 2s. 6d. The effect of this is to bring the societies into closer competition with the class of landlords before spoken of.

Some of the causes which tend to render such property unremunerative are beyond the control of any interference, as, for instance, the increasing value of land and buildings in the great centres of industry and the excessive wear and tear of buildings inhabited by poor tenants. The other causes may be classed under two heads—1. Those which may be removed or modified by the legislature. 2. Those which must be remedied, if at all, by increased care and experience in the purchasing of sites, and in the erection of buildings, and in the placing them under economical and efficient management.

The Committee at the outset of their deliberations determined to direct their attention principally to the first of these two classes, with the hope that they might be able to suggest such amendments of the law as would secure to capitalists investing money in this kind of property a fair return on their capital.

Among the burdens which press upon the owners of houses or blocks of dwellings for the labouring poor are the following:—

RATES AND TAXES.

It has been commonly put forward, and is very gene-

rally supposed, that the amount of taxation, local and otherwise, to which property of this kind is subject, is so large as materially to affect the returns which a capitalist or builder would calculate upon as remunerative when contemplating the erection of dwellings for the labouring classes.

It appears to your committee, after investigating the accounts connected with a considerable number of such dwellings, that the total amount of taxation from all sources does not exceed 1½ per cent. on the whole capital invested, an amount which (even if the exemption from the whole of such taxation were practicable) is too small to exercise any appreciable influence on those contemplating the investment of capital in an undertaking of this nature. Under these circumstances, and considering the violation of sound principles involved in making any exemption in favour of any particular class of house property, the Committee do not feel justified in proposing the adoption of any measure of exemption.

The house duty may be usually avoided in blocks of buildings whose size would otherwise make them liable to it, by giving to each set of apartments a door opening to the external air, and making them thereby a distinct tenement. This is called the external gallery system.

PARISH RATING IN THE COUNTRY.

The question of charging the relief of the poor on the parish or on the union, is one which peculiarly affects the building of cottages in the country. The present system has long been found one of the greatest obstacles to the proper accommodation of labourers on the estates on which they work; and the committee were prepared to recommend an amendment of the law by the extension of the chargeability of the poor from the parish to the union. It is a gratification to the committee that the same views on this important question have been generally recognised by the legislature, and that they are likely to be carried into operation by the Bill now before Parliament. The committee confidently expect that many good results will follow from the adoption of that measure.

PARISH RATING IN THE METROPOLIS.

It was a subject of consideration by the Committee, whether similar good results would not be produced by extending the area of chargeability in the metropolitan districts. In the discussion of this question the committee were much aided by statistical tables furnished by Mr. Farnall, and by his large experience in this subject. It appeared from these tables, in which the amount of the poor-rates were reckoned according to their proportion to the gross rental, instead of on the present capricious system of assessment, that the pressure of the rates on property in the metropolitan parishes is not so unequal as is generally supposed; and in the opinion of the committee the inequality which really exists does not in any perceptible degree form an obstacle to the erection of dwellings for the labouring poor. Whatever other causes, therefore, may exist to render it desirable to extend the area of chargeability in the metropolis, the committee do not think that such extension will produce any sensible effect in furthering the object specially under their consideration.

STATE OF THE LAW OF REAL PROPERTY.

Some very interesting discussions took place on the difficulties the present state of the law of real property interposes in the way of those who are desirous of providing dwellings for the labouring poor, and of labourers who wish to become the owners of the dwellings in which they reside.

Much of the land in London and other large towns belongs to Charities and other Corporations and persons under disability, or is in strict settlement. Much has been done by modern legislation towards enabling trustees of settled estates and limited owners to grant building leases, and to sell portions of the estate for the benefit of

the rest, under the direction of the Court of Chancery. But, independently of the expense of an application to the Court, there are many cases which are not met by these enactments.

The Committee suggest that corporations, limited owners, and persons under disability should have similar powers of selling small pieces of land for improved dwellings for labourers as they have now for selling sites for schools—(under the 4 and 5 Vict., c. 38, &c.), and for literary and scientific institutions, under the 17 and 18 Vict., c. 112).

The Committee had the advantage of the presence of Mr. Hare to explain his scheme for encouraging the investment by labourers of their savings in the purchase of sets of rooms in large blocks of dwellings. He proposes that each block of dwellings should be registered under the Land Registration Act, and should obtain a certificate of indefeasible title; that when that is done, the building should be withdrawn from the ordinary laws and incidents of real property, and should become personal estate; and that the apartments in it should be transferred as separate tenements, in the same manner as stock is transferred in the public funds. In this way he hopes that the tenants would become absolute owners of the rooms in which they live, paying off the purchase money in a limited period by instalments, very little greater in amount than their rent as weekly tenants. He also proposes that the management of the entire building should be vested in a committee chosen from the owners of rooms, who would regulate their mutual rights and liabilities, and enforce the good preservation and repair of the rooms and the orderly conduct of the inhabitants.

The Committee agreed in the expediency of any mode of facilitating and cheapening the conveyance of small tenements, but they considered that the difficulties and embarrassments, both to seller and buyer, which would arise out of any plan by which the apartments in a large block of buildings would become vested in individuals of the labouring class, would outweigh any benefit which might arise from it. The danger of such small tenements falling into the hands of speculators, who might take advantage of the necessities of the original owners; the obligation under which the working classes live of continually and suddenly changing their residence in search of work, the probability that the rooms would not be so well kept as when owned by a company; and the difficulty of arranging the mutual interests of so many small independent freeholders, seem to the Committee insuperable objections to the scheme.

At the same time there appears to be nothing in the present state of the law to prevent a company owning such a block of dwellings, after they have obtained an indefeasible title, from letting the sets of rooms as separate tenements on leases of any duration, subject to proper sanitary arrangements; and the Committee believe that such a plan might, in many cases, be desirable. In such a case, the tenant would secure the benefit of a lower rent than if he were a weekly tenant, and would acquire the feeling of property in his own home; while, at the same time, the company would be secured by covenants and powers of entry against dilapidations and misuse of the tenement.

LOANS BY GOVERNMENT.

Numerous Acts have been passed, commencing with the 57 Geo. III., c. 34, for enabling the Public Loan Commissioners to advance money at a low rate of interest for public works and the employment of the poor, the money borrowed being repaid by instalments in a limited period. The 9 and 10 Vict., c. 79, is the Act which regulates the present practice. By the 23 and 24 Vict., c. 19, the Public Works Acts (Ireland) were extended to authorise the advance of money for building cottages for labourers in that country. In England the Public Loan Commissioners have never been authorised to advance money for that purpose; but by

the 9 and 10 Vict., c. 74, they are enabled to lend money to vestries on the security of the rates for building public baths and washhouses. By the 14 and 15 Vict., c. 34, the same Commissioners are also empowered to lend to boards of health, and other local authorities, in like manner, money for building lodging-houses for the poor; this Act, however, is encumbered with so many conditions that it has been practically inoperative.

There is also another series of Acts (9 and 10 Vict., c. 101, &c.), enabling the Inclosure Commissioners to advance money in the same way to landowners for drainage and improvement of land; and under the Private Advance for Drainage Acts (27 and 28 Vict., c. 114, &c.), tenants for life, and other limited owners, can borrow money from private sources for the same purposes. The Inclosure Commissioners appear to have no power to advance money for building cottages, but this may be done by the Drainage and Land Improvement Companies.

So far, therefore, as relates to cottages in the country, the committee do not desire any alteration in the law, but they recommend, with respect to labourers' dwellings in towns, that the public Loan Commissioners should have power to advance money at a rate of interest not exceeding 3½ per cent., for building such dwellings, with due regard to sanitary arrangements. The committee believe that by such assistance the promoters might be enabled to add materially to their profits, and that the building of such dwellings would thereby be much encouraged.

DEMOLITION BY RAILWAYS, &c.

The effect of the demolition of the homes of the poor by local improvements and by metropolitan railways has been lately very much before the public. In the Earl of Shaftesbury's speech on the 31st March, in moving for an amendment of the standing order of the House of Lords upon this subject, his lordship stated that the houses for the demolition of which notice had been given under the bills before Parliament in the present session, amounted to 3,500, containing a population of 20,000 persons.

Although a large number of these houses will not be actually destroyed, being merely included within the limits of deviation, yet the numbers give some, though an imperfect, idea of the vast amount of inconvenience and distress such works must produce among the poor. It has been proved, by careful inquiries on similar occasions in former years, that a very large proportion of those who are displaced do not leave the immediate neighbourhood, but crowd still more the already over-crowded dwellings of the same parish. And, in most cases, the Committee believe that this is not merely a temporary evil, because the necessity of being near their work forms an obstacle to their dispersing into more distant places.

It is the opinion of the Committee that where public companies destroy houses inhabited by the working classes under compulsory powers, they ought to be compelled to provide sufficient improved dwellings within a convenient distance for the same classes in place of those destroyed, and that they should have special powers given them for that purpose.

An evil is likewise sometimes perpetrated by railway companies, though probably to a comparatively small extent, by taking the yards or back premises of houses and reselling them for occupation by labourers, with reduced sanitary accommodation. The Committee are of opinion that in such a case the company should not be allowed to sell such houses without making provision for their proper ventilation and for the sanitary accommodation of their inmates.

WORKMEN'S TRAINS.

Another plan for relieving London of some part of its overcrowded population is to encourage labourers and their families to live a few miles out of London, and to trans-

port them to and from their work in the morning and evening by cheap trains. The number of small houses now building in the suburbs of London is very great, and as working men discover by experience the advantages arising from improved health to themselves and to their families from living away from the crowded streets where they now lodge, the demand for them must increase; but even this improvement will be but temporary, and will shortly produce a new set of evils, unless the erection of these houses be carefully watched and their drainage, ventilation, &c., be properly attended to. Precautions against overcrowding will also be as much required as in existing houses. The Metropolitan Railway Company have been trying the experiment of running workmen's trains for some months with marked success. They provide early trains from Paddington and from the City, which are used almost exclusively by working men, and they allow them to return by any train in the afternoon. No inconvenient restrictions respecting tickets are imposed, and the weekly increase of numbers is very satisfactory, and when the system is extended to Hammersmith still better returns may be anticipated. The London, Chatham, and Dover Railway Company have done the same, in pursuance of a clause in their Act, since the beginning of March. From a statement by Mr. Forbes, the general manager, in a letter quoted by Lord Shaftesbury, in his speech before referred to, it appears that the number of workmen carried by their trains has increased week by week; but the unnecessary restrictions imposed by this company upon the men using these trains must be removed before the low rates will be profitable to the company, or available to any important extent, to workmen.

The Committee desire to express their decided opinion that it would be for the benefit of the community at large that all the metropolitan railway companies should provide cheap means of transit, at convenient times, for labourers; but they hesitate to recommend that this should be made compulsory in all cases, believing that if their views of the results likely to arise from such accommodation to the working classes be correct, the directors of the railway companies will not fail to adopt them.

There is also another view of the subject which must be noticed by the Committee, namely, the tendency of manufacturers to remove their works from the crowded centres of large towns to suburban districts. Such a practice is likely to produce very beneficial results. While healthier dwellings are provided for those who work in the manufactories, the overcrowded condition of those who are obliged to remain in the heart of the cities will be proportionally relieved.

ENFORCING THE SANITARY LAWS.

Whatever progress may be made in building or adapting houses by individuals or societies, the great mass of the labouring population for many years to come must necessarily live in very crowded neighbourhoods, in houses now existing, and not originally adapted to contain several families under one roof.

It is, therefore, of the first importance that the owners of existing houses, inhabited by the poor, should be obliged to provide those sanitary appliances which are required for the preservation of the health of their tenants, and to check, when it occurs, the progress of infectious disease. Long experience has shown that nothing but constant inspection and compulsory measures will meet the carelessness and cupidity of the owners of this kind of property.

The present sanitary laws are comprehensive, and on the whole efficient, although there are some particulars in which the Committee think they require amendment, especially with relation to the inspection of houses let to lodgers, but not now subject to the provisions of the Common Lodging House Act. The provisions of the sanitary acts are not, however, sufficiently known, nor do those who are qualified by intelligence and position to attend to the

sanitary condition of their own neighbourhood interest themselves as much as could be desired in seeing that the powers of the law are put in execution.

The Committee recommend that a concise analysis of the sanitary laws should be prepared, and that the defects of the existing law should be printed and circulated. In this way the attention of men of education and intelligence would be called to the subject, and they might be induced to take part in sanitary work in the neighbourhood in which they reside or carry on business.

In the country districts the sanitary condition of the people is regulated by the Nuisance Removal Acts, 18 and 19 Vict., c. 121 and 23, and 24 Vict., c. 77, and the Local Government Act, 21 and 25 Vict., c. 98; the power being vested in the Local Board of Health, or, if there be none, in the corporations of towns, boards of guardians, or parish vestries, according to the circumstances of each locality.

In the City of London the power is vested in the Commissioners of Sewers, under the Acts regulating the administration of the City.

In the other Metropolitan districts the vestry or district boards are the local authorities for the removal of nuisances, under the Metropolis Management Acts, 18 and 19 Vict., c. 120, and various Amendment Acts.

By the 21 and 22 Vict., c. 97, the powers of the General Board of Health were transferred to the Privy Council, which has a general superintendence of sanitary matters. This branch of their duties is practically exercised by the medical officer of the Privy Council. The committee think that there should be a committee of the Privy Council constituted as a separate department, to which appeals might be made from the local authorities, and whose duty it would be to consider the recommendations dictated by the experience of the district medical officers.

They also recommend that the appointment of proper inspectors of nuisances should be compulsory in all places, so that it should be the duty of such inspectors to report forthwith to the local authorities all nuisances which exist without waiting for the complaint of other persons.

The Committee further recommend that the medical officers of health should be irremovable without the consent of the Privy Council, and that the amount of their salaries should be subject to the approval of the same authority. The duties of these officers, if properly performed, are liable to bring them into collision with the interests of persons having influence in the vestry, and it appears of great importance that their independence of action should be secured.

It appears also to the Committee, that both the Nuisance Removal Acts, and the Metropolitan Management Acts, are deficient in not giving to the local authorities sufficient powers to oblige the builders of houses to make proper provision for drainage and ventilation.

The 29th section of the Nuisance Removal Act (18 and 19 Vict., c. 121), also requires amendment. It gives power to the local authorities to take proceedings against the owner of a house inhabited by more than one family, if it shall be found to be overcrowded; but it leaves in doubt the case where particular rooms in a house are overcrowded, as well as the case of a single family in a small house of one or two rooms. It is however to be remarked that the medical officers find it impossible to interfere as they wish with the overcrowding of houses, because of the difficulty. It should rather be said the impossibility, of the poor finding accommodation elsewhere. In this as in other details of sanitary inspection, over-strictness may become oppression, and aggravate instead of alleviating the hardships of the poor. Until more and better dwellings are provided, and until the labouring classes have learnt more fully themselves to appreciate the blessings of air and cleanliness, no sanitary regulations can be satisfactorily carried out.

The Committee in conclusion recommend to the Council:—

1. That corporations, limited owners, &c., should have increased power to sell land for the erection of dwellings for labourers, under conditions as to proper drainage, ventilation, and sanitary regulations.

2. That the public loan commissioners should be authorised to lend money, at a rate not exceeding 3½ per cent. per annum, for building dwellings for the labouring classes, under suitable guarantees and with due regard to sanitary arrangements.

3. That in all future railway acts, and acts for local improvements, when houses inhabited by the working classes are destroyed under compulsory powers, such companies should be compelled to provide, within a convenient distance, other dwellings in lieu of those destroyed.

4. That the following amendments should be made in our sanitary laws:—

a. That the appointment of inspectors of nuisances throughout the country should be compulsory.

b. That increased power be given to the proper local authorities, to oblige builders of houses to provide adequate drainage and ventilation.

c. That the medical officers of health should be irremovable without the consent of the Privy Council, and that the amount of their salaries should be subject to the approval of the same authority.

d. That houses in which lodgers are taken, especially where particular rooms in a house are overcrowded, should be brought under more efficient inspection.

5. That with the view of extending an accurate knowledge of the powers contained in the various acts relating to the removal of nuisances, the Council is recommended to prepare and publish a concise analysis of the existing law, calling the attention of the educated classes to this important subject, and pointing out how they may, merely by a little attention and exertion, confer most important benefits upon a large mass of working people and upon the country generally.

6. That the Council be requested to take such measures as it may think advisable to bring the first four of these recommendations as soon as possible under the notice of Her Majesty's Government.

(Signed) W. HAWES, *Chairman*.

3rd May, 1865.

TWENTY-SECOND ORDINARY MEETING.

Wednesday, May 10th, 1865; William Hawes, Esq., Chairman of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Homan, Julius, 85, The Grove, Camberwell, S.
Hunt, Alfred Terrett, 1, Encombe-terrace, Wandsworth-road, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Bean, Alfred W., Danson-park, Welling, Kent, S.E.
Dent, William, 21, Newcastle-street, Strand, W.C.
Gover, William, Italian-villa, Lee-road, Blackheath, S.E.
Hancock, C., 6, St. Germain's-villas, Lewisham, S.E.

The Secretary called attention to a respiratory apparatus, invented by M. Galibert, who was present and showed its action. A description of it will be found at page 440.

The Paper read was—

ON THE ART OF LAYING SUBMARINE CABLES FROM SHIPS.

By CAPTAIN JASPER SELWYN, R.N.

I venture to claim your attention this evening for the purpose of considering a subject, the importance of which, at the present moment, can scarcely be exaggerated.

A renewed attempt is about to be made to connect, by a submarine electric wire, the intelligences and interests of the old world with those of the new, and no enterprise of this age promises so much benefit to the whole human race as the realisation of such a method of instantaneous communication. The subject, therefore, may fairly be considered as one well fitted to interest the members of a society devoted to the cultivation of the Arts—the highest art being that which is calculated to benefit mankind; while, on the other hand, by no other body could the views for which a hearing is sought be more fitly stamped as current coin or repudiated as base metal. But that I am aided by the observations of some of the first mathematicians and the most celebrated engineers—of this or any other country—if I had not secured the direct support of many of the most distinguished members of my own naval service—I should scarcely have dared to advance here what might be stigmatised as crude opinions or ill-considered theories. Yet I feel that I must ask your indulgence if, while asserting some things with the enthusiastic feeling which must animate every officer of my profession who thinks that he may perchance contribute something, however small, to the solution of a great nautical problem, I should fail adequately to explain, in all cases, points where the apparently intuitive knowledge of a seaman leads him confidently to predict results for which to the landsman's mind there seems no sufficient cause.

It will readily be conceded that just as no railway could be constructed with any chance of economy or ultimate success, unless after the most careful surveys and calculations—as, again, any fundamental error in such calculations would deserve the most careful elimination—so in this great work of laying an Atlantic telegraph cable, which is immeasurably more difficult, it behoves us to examine and re-examine the bases on which we are to proceed, and to refuse attention to no suggestion, from whatever quarter it may come, until we are absolutely convinced of its worthlessness.

Among those considerations which, as I hope to show, may most favourably or most fatally influence the success of the delicate operation of laying a comparative thread of electric communication across the Atlantic, the curves described by the cable in sinking may claim the very foremost place. The question first to be solved is—Is the path of the cable during its descent to its ocean bed a straight line, an upward, or a downward curve? Is it an inclined plane? Is it a parabola with a small curve of contrary flexure? Is it, or when is it, a catenarian curve?

As no less an authority than Professor Airy has held and published the last-mentioned opinion, I will, if you please, consider that case first. A ship at rest in an ocean of two miles in depth, allows a sounding line, carrying an iron weight of 96 lbs., to run freely to the bottom. By many and accurately made experiments we find its time of descent to be fifty minutes nearly. We may treat it roughly, for our present purposes, as two nautical miles per hour. Now we can by no means expect that any telegraph cable, more especially the present Atlantic (a specimen of which is on the table), could sink at a materially greater rate. More probably it would be considerably longer in reaching the bottom. But we will assume that it sinks as fast. Then, in one hour, a cable which is being paid out without strain, will reach the bottom in two miles depth of water. If, during that hour, the ship has made a progress of only one mile, and the natural acceleration of the descending cable has not been interfered with by brakes, the curve described will inevitably be a catenarian one; and this will be the case whenever, no strain being kept on by mechanical appliances, the rate of sinking of the cable is in excess of the rate of progress of the ship. It is always thus in shallow water with heavy cables; a catenarian curve is there the invariable rule.

Next we will consider under what circumstances the cable will pursue a straight path, on an inclined plane, to

the bottom. If the rate of sinking of the cable be again assumed as two miles per hour, and any rate of speed be given to the ship less than or equal to this, while a strain by brakes is placed on the issuing cable sufficient to prevent acceleration beyond the speed at which it is dragged out of the ship, then the line of descent will be a straight one, or little varying from an inclined plane. But in both these cases we have assumed a speed of ship of two miles only per hour, which in practice would be inadmissible.

We will now pass on to the case in which, as always really occurs in practice, the speed of the ship is materially greater than the rate of sinking of the cable. The cable issues from the ship, still under some strain, at from 20 to 30 per cent. in excess of her speed, which we will call five miles in the hour. That is, in one hour the ship has passed over five miles of ground, two miles of the cable has sunk, and, say, six miles of it has been paid out, or has issued from the stern of the ship. What has become of this? and in what curve, or on what inclined plane, is it now arranged? This, so far, is the real point at issue. I venture to hold that the curve which under these circumstances takes place is an upward one, of the nature of a parabola, having a small curve of contrary flexure near the bottom, the general convexity being towards the surface. My reasons for this opinion are as follows:—First, whatever may be the speed of the ship, the rate of sinking of the cable can never be increased correspondingly, or, indeed, in any degree. Secondly, the slack paid out, averaging 25 per cent., is very much more than the difference between the horizontal distance, five miles made good in one hour, and the diagonal distance from the surface to the bottom on the same route. And this excess will certainly not be expended in producing a serpentine form, for which there is no possible cause, unless a very large proportion of slack is paid out, but in that upward curve, the cause for which is to be found in the resistance to cutting descent of the fluid through which the cable is moving. The less the sp. gr. of the cable, and the larger its diameter, the longer will be the comparatively straight part of the parabola, and consequently the more cable will be exposed to the effect of lateral surface currents wherever such exist.

Indeed, a valid proof that there is a considerable portion of the cable so exposed to currents, and, therefore, that there is such an upward curve, is to be found in the fact that on several occasions the issuing cable was run away with by a comparatively trifling current, making it take an angle with the ship's course. This could not have been the case had only the small portion of cable been exposed to the effects of currents, which would be due to the cable following an inclined plane between the ship and the bottom. This upward curve would also be liable to be produced or increased when there existed a current in a direction opposed to that of the ship's progress, for then there would be an increased resistance to cutting descent. While I thus attempt to show what is probably the curve taken by the cable, and what are the dangers attendant upon it, how it is produced, and what are its limits, I also wish to point out that, if this be the truth, there is an important advantage which may possibly be realized in case of a breakage of the cable. We all, I am sure, sincerely hope that this may not be the case, but should it occur, with proper apparatus attached to a strong hawser or line, and by steaming, so soon as the signal of rupture was heard, directly across the track previously followed by the cable-laying vessel—her consort, whose station should always be about three miles on the lee quarter, might catch the cable again before it was irreparably gone. I exhibit some apparatus for doing this automatically, and without such assistance; but there will be considerable difficulty in using it, unless by men of great nautical skill.

I propose now to consider the lateral curves, with their effects, which may be made by the cable, owing to surface currents at an angle to the ship's course. If, the ship's course being west, a surface current be entered whose di-

rection is southerly—towards south, *i.e.*—no effect can be noticed on the ship herself until, by astronomical observation, the existence of such a current is evidenced in the difference between the true and dead reckoning position; but it is otherwise with the issuing cable. It may immediately be observed to have deviated from its former line straight astern, and is now carried at a greater or less angle on the port or left-hand quarter; also, the strain shown by the dynamometer and the rate of issue will rapidly increase. Now no more fatal error can be committed by the engineer than to load the breaks, and attempt to resist this. The only remedy is to go faster, steer a current course, and get out of the current as soon as possible, yielding so much to the increased demand for cable as never to bring more than a very small strain on. But it may be objected that, by so doing, an enormous percentage of slack will be lost. It is so apparently, but not really; for, as the current is but a surface disturbance, so soon as the cable in sinking has passed through it, the line in which it is laid follows really the true track of the ship as she is carried by the current, although, while in the current, it is carried in a loop far away to leeward. This it is very difficult to explain clearly without a diagram or model, to which I must therefore refer you; but it results from the fact that the cable exposes a very large surface to the lateral action, and is not like the ship forced against it by the motive power. If we conceive a fluid surface like oil floating on water of a certain depth—that this oil is carried laterally at a given rate by a cause which does not affect the water under it; if next we imagine a cord laid over the oil and sinking first through it and then through the water, we shall be able to understand how in the oil the cord may be carried off in a loop, or bight, as it is called by seamen laterally, falling thereafter through the water in the true line in which it is laid. But, of course, this will only be the case where the current has no great depth, for if from top to bottom the whole body of water moved, there must be a uniform lateral curve, just as there is a vertical one owing to the resistance to cutting descent.

It will be useful to remember that the new Atlantic cable, having a diameter of one inch and a quarter, exposes about 633 feet of section per mile, and a two-knot current at 11·8 lbs. per square foot brings a strain upon each mile exposed to it, of over three tons. Now, as in yielding to the set of the current more and more cable will constantly be demanded, and therefore more will be exposed to it (the rate of sinking never being capable of increase), it would at first sight appear that this demand ought to be resisted; and, in the first attempt at laying, there was an instance in which this course was pursued, which, as I should have expected, resulted in the breaking of the cable. I hope that so unwise a proceeding will not be repeated. It should be a rule with those who are laying deep-sea cables, that the maximum allowable strain must never exceed one-fourth of the breaking strain, even where the cable is made comparatively inextensible by the use of longitudinal fibre or wire; but where spirals of iron or steel wire enter into the construction of a telegraph cable, not being in contact with an incompressible core, then no strain sufficient to stretch the copper wire, which is now acknowledged not to be protected from such tension by any spirals,—I say no strain, not even that due to its own weight in any great depth, can safely be borne by it. Again, the rule of the cable-maker ought to be that, his cable being hung freely in air, the weight is to be accurately observed which suffices, not to break it, but to stretch it two per cent., and on no account must more than a half of this be afterwards brought upon it.

If, after accurately calculating the number of pounds of copper per mile which will carry messages a certain distance at a certain remunerative rate, I then subject that wire to any tension which can decrease its area, and do so, moreover, to an uncertain extent, at any place where the wire, although seven-stranded, happens to be unusually soft, I might as well not have calculated, for I cannot

secure the result. Therefore, even one per cent. of stretching is to be avoided if possible. There is no other way of doing this than by adopting either straight steel wires, enclosed in an elastic compound, as in Mr. Macintosh's cable, or less perfectly, but probably sufficiently near inextensibility, by the steel spiral in contact with the incompressible copper conductor of Mr. Allan.

The next branch of my subject to which I will beg your attention is the formation of kinks. The causes for their formation are various, the process of coiling and uncoiling being the first. The means of avoiding those so caused, while securing many other advantages, I have so often brought before the public that it would unnecessarily detain you if I were to do more than point out the model and diagrams of the floating cylinders which I have always consistently advocated. But there are other causes for kinks which might be avoided. No treatment could well be more unfavourable for a telegraph cable than that of forcing it to pass round comparatively small drums from four feet to eight feet in diameter, as brakes under a heavy strain, and none could be found more certain to induce the formation of those kinks which are so much to be dreaded. Now, kinks thus formed may occur under water, after the cable has been lost to sight in the waves, and this will happen most often when the ship is pitching, and so suddenly slackening up the cable which then, not being able to sink faster than it did before—being, in fact, partially water-borne—arranges itself into a curve such as it had when tightened round the drum. The next upward pitch produces a kink which may, if it does not break the cable, yet cause inside the elastic sheath solution of electrical continuity. This recovers itself temporarily at the end of an hour or so, when the strain is taken off by the approach of that part of the cable to the bottom and the ends of the broken copper wire come together again, only eventually to be destroyed by the accumulation of electrical resistance at that point.

Now this can be in part avoided by the use of an elastic connection for the retarding apparatus—I will not call it by the ill-omened name of brake—nor should it be in any way similar to those machines which have been hitherto used for such purposes, but rather like the human hand with the difference that the rubbing surfaces must be rolling surfaces also. By such means there must be established a continual give and take of the cable whenever the ship is pitching heavily, as even the *Great Eastern* may do if she gets a sea on the quarter or bow. It should not be forgotten that the danger of bad weather will, in this instance, be double what it was in the *Agamemnon's* case, because the time occupied by one ship in laying must necessarily be twice as great as when two are employed starting from the mid-Atlantic.

I am sure that every one who is interested in the spread of Ocean Telegraphy, not alone those who are peculiarly interested, but also that far larger body who feel that the more rapid communication of thought must sensibly influence the happiness of the whole race (and to that body who does not belong?) unite in wishing success to the renewed attempt to unite England and America by an electric cable. Of the advantages to the fortunate company who shall succeed we have often heard; there is little doubt that one year's good work would pay the whole cost. But immediately after such success ocean telegraphy would stride where hitherto it has only crept, and then we all trust that each who has some idea on the subject which would secure diminished risk or cost, will have a fair chance of seeing (if it be really good) his pet project brought into practical use. Now my pet is a drum, not, as you have heard to-night, a small one, but one so large as to have been objected to on that score, and which I have promised you not to beat to-night. But you will not, I am sure, object to my mentioning another pet, of quite a different character. No one deserves more credit in connection with submarine telegraphy, for the money they have

expended and the perfection they have attained, than the manufacturers of insulating substances; and I fully believe that whatever was possible has been done by the India rubber manufacturers for caoutchouc, and by the Gutta Percha Company for their admirable gum. But new materials of hitherto unattainable qualities must make themselves felt in every social want, and the discovery of paraffin, and its power of combining with India rubber in small proportion, bids fair to revolutionize the whole system of insulating cables. Not only is the insulation better, but the inductive capacity is less than the best virgin Para rubber, while, for plasticity and durability, it surpasses any gutta percha. More than this, the price at which it can be manufactured will leave these gums far behind, and its general adoption can only be a question of time.

I will conclude by saying that, in my opinion, there ought to be no difficulty in laying telegraph cables wherever required; that there is no reason whatever for preferring along shore lines, but the contrary; and that if we can only hail the success of the Atlantic cable this year, half-a-dozen more cables will immediately be required. I hope that the questions I have raised here on this occasion will have a value stamped on them by discussion such as my feeble efforts could never give; and thanking you for your kind attention, I trust you will believe that my aim has been and will always be "to assist a known friend in view," in the language of the Articles of War, to the utmost of my power and ability.

DISCUSSION.

Mr. VABLEY expressed his opinion that the cylinder or drum introduced by Capt. Selwyn, for the purpose of laying submarine cables, was the best plan that could be adopted, as the cable was thus subject to less mechanical disturbance than was occasioned by the means usually employed. The merits of Capt. Selwyn's system were, in his opinion, so great, that he wished it every success.

Mr. C. W. SIEMENS said they must all feel much indebted to Capt. Selwyn for having brought this subject so fully and ably before them. He (Mr. Siemens) could not, however, go so far as to say he entirely agreed with him in all his statements. The curve made by the cable while being laid was no doubt a very important consideration in dealing with this subject, and he did not agree with Capt. Selwyn that its form was such as he had described it to be. He thought it was capable of demonstration, that when a ship was proceeding at a uniform rate of speed, and paying out a cable of fixed density, the latter must descend in a direct inclined plane. Capt. Selwyn had stated that the moment the cable left the ship it would commence its downward course, at the rate of about two miles per hour; then, if the ship was going at six miles an hour, the inclination at which the cable would remain would practically be 1 to 3, or if it went at four miles an hour 1 to 2, or if at two miles an hour 1 to 1; so that, unless the velocity of the ship changed, the cable must descend nearly in a straight line. Then came the question why it was found impossible in practice to do without a certain retarding force during the operation of laying. While the cable was, as it were, sliding down the inclined plane, the force exerted was so great that, if it were not resisted, it would cause the cable to run out with such velocity as to produce an immense waste of cable. When it got to the depth of 1,000 fathoms the force with which the cable ran out was very great indeed, and it required to be resisted, otherwise twice or thrice as much cable as was required would be paid out. He thought it was of comparatively little importance what method of paying out was adopted so long as it was a safe one, affording the means of varying the retarding force at will. It appeared to him that the great point was to make the apparatus as simple as possible, so that no kinks or other disturbances could arise. With regard to the measure of the retarding force, that would depend entirely upon the specific gravity of the cable

and the depth. The laying of a heavy iron-coated cable in 2,000 fathoms water was a difficult and critical operation. One of very small specific gravity might perhaps go out nearly in the upward curve described by Capt. Selwyn; and if it did so, although there was no retarding power acting upon it, there would be danger that sufficient slack would not be produced at the bottom. Then came the considerations as to the nature of the bottom. If the cable were laid along a great plateau, then moderate slack was sufficient, but with a precipitous bottom, it was difficult to lay out sufficient slack for the safety of the cable. He would mention a case which came within his own knowledge. A cable had to be laid not far from the Spanish coast, and, according to the soundings previously taken the bottom descended in a slope of about one in four, but it turned out that in reality the shore was very mountainous, and of a volcanic nature. At about eleven miles out at sea, there was a deep valley with precipitous sides. The depth of one edge of this valley was about 700 fathoms; of the valley itself 1,600 fathoms, and of the other edge 900 fathoms, so that the cable was suspended between the two precipices, involving great danger of rupture, which actually did take place shortly after the cable had been successfully laid. In cases where such gulfs were known to exist, the only safe plan was to stop the ship, and allow the cable to run out so as to furnish enough to lie on the bottom at every point, however deep. This was a serious source of danger, against which it was important that every precaution should be taken. Deep sea soundings were not generally taken at sufficiently frequent intervals, and cables were seldom laid in the line of soundings.

Mr. THOMAS ALLAN felt much obliged to Capt. Selwyn for bringing forward this interesting paper on the art of laying submarine cables, but it occurred to him (Mr. Allan) that the solution of that problem involved the solution of another, viz., that of the art of making the cable itself. Cables had been made, and were being made, every day, which, so far as their electric conditions went, were suitable for communication with the other side of the Atlantic. The last Atlantic cable, when constructed and on board ship, did its work well enough; but before it got well to the bottom of the sea its occupation was gone, or it experienced such an amount of deterioration, that after it had lain a short time on its ocean bed, it "gave up the ghost," and ceased to be of any use. His own opinion was, that the first element in a deep sea cable was that its specific gravity should be so low that the apparatus required for the laying of it should be something wholly different from what had hitherto been employed. Up to the present time it was a misnomer to say cables were paid out. They were, in fact, dragged out, and were always kept on the stretch, so that (as had been described by Mr. Siemens) on crossing a chasm they were suspended from one point to the other, at the risk of great injury. Hitherto the main point in the construction of a cable appeared to have been to enclose the electrical conductor in one of two destructible materials—iron or hemp—or in both together. For his own part, he thought it an absurdity to employ a destructible material like iron to protect an indestructible material like gutta percha. It had happened in the Mediterranean that cables after being laid for a short time had ruptured, probably from having been suspended over a chasm, but if these cables had not been burdened with such heavy materials they would probably have remained suspended, and no destruction of the electric continuity had taken place so long as the gutta percha remained sound. If a cable of sufficiently low specific gravity were made, the operation of paying it out would be an easy one. It might be pitched out of a ship as a fisherman would throw a line from a reel. There ought to be no strain put on it, and it should be let out at a rate 14 or 15 per cent. faster than the speed of the ship, so that it might find its way to the bottom in its own good time. There was no reason why it should not arrive at the bot-

tom of the sea in the same electric condition as when it left the ship. A shallow water cable was a different thing altogether, and called for a different mode of construction. Results proved that nearly all the cables made of a single conducting wire had been failures, while the multiple wire cables between this country and France and Holland had all been successful, simply because, as shallow water cables, their mechanical construction was correct. Of the 15,000 to 17,000 miles of cable laid up to the present time, there were not more than 4,000 miles in working order, and 2,500 out of the 4,000 were of the type of the present Atlantic cable; but that type of cable, wherever it had been attempted in deep water had failed from the stretching. He very much regretted, notwithstanding the experiments instituted by the Government commissioners, that that form of cable had been decided upon for the Atlantic route. The same type of cable had been adopted from Toulon to Algiers and Corsica, and both had failed. In the first place there was considerable difficulty in laying it, and though it was made of comparatively low specific gravity, so as to make it suitable for deep water, it kinked to a great extent. The late Atlantic cable was of such a construction as to be liable to stretch, and that impaired its conducting power. He sincerely hoped the present cable would be successful, but he could not say he had much confidence in it—many causes might rupture it before it got to the bottom, and even if it arrived safe there he was afraid it would not satisfy the requirements of the public.

Dr. BASHHOFFNER remarked, with reference to what had fallen from the last speaker, that they had been told by Capt. Selwyn that he believed if the present Atlantic cable succeeded the whole cost of £800,000 would be repaid in one year, but from what had been said by Mr. Allan, who was a great authority on these matters, the failure of that enterprise might be looked for long before the £800,000 was earned. Mr. Siemens, who was a great authority in the laying of cables, differed from some of the statements made by Capt. Selwyn, and had put a very remarkable case before them in support of his own views with respect to the great valleys or gulfs met with at the bottom of the sea. Mr. Allan had spoken in favour of cables of low specific gravity, but he (Dr. Bashhoffner) thought that was hardly the type calculated to withstand the great resistance which a long cable like the Atlantic would meet with. The casing of a cable with iron was desirable—first, for obtaining a certain degree of specific gravity, and secondly, to withstand any injury it might meet with when laid down. There was one circumstance connected with this subject which had not yet been noticed. They were told on the preceding evening in this room, by Dr. Grace Calvert, of the effects that were produced upon iron by friction and percussion, by which a body not crystalline in its natural condition became so by constant motion, and the familiar example of the crystalline state of the axles and tires of locomotives was given in support of that view. Some years ago he was much engaged in manipulations with large voltaic batteries, the wires of which were as thick as a goose-quill, and composed of the best and most flexible quality of copper, but after a few months' use those wires became so brittle that they broke off short like a piece of dry stick. He thought it was generally admitted that the action of electricity through these conductors was a vibratory action, and not a direct transmission of the force. It was by molecular action that electricity was conducted through the wire, owing to which it resulted that the wire became in a short time converted from a fibrous into a crystalline state; and he believed it would be so with the electric conductors in cables, in proportion to the work to which they were subjected, or in proportion to the amount of electricity transmitted; and thus there might be danger that, after long use a very slight accident in the water would easily cause rupture. Capt. Selwyn had mentioned the curious circumstance that a cable in being paid out might be so stretched as to cause an interval between two points of

the conducting wires, but that as the cable contracted again after it was relieved of the strain these would be brought together again. That was alleged to have been the condition of the late Atlantic cable. They knew if there was an absolute break of continuity of the conductor only a small spark would be transmitted from one point of severance to the other, and eventually so much oxidation would take place as to destroy the conducting power of the cable.

Mr. MAORINROSE said he thought that, from the care the electrician was taking in testing the new Atlantic cable in tanks under water, there was no doubt that, when the *Great Eastern* left Valencia for Newfoundland, the electric tests would be perfect. The paying-out apparatus was of an exceedingly delicate character, and he believed a tolerably accurate survey of the bottom had been made, so that he had little doubt but that the cable would remain practically useful for some time at least. The tarred hemp covering would, however, cause great delay in the sinking of the cable, particularly if it met with surface currents. If the *Great Eastern* encountered bad weather, the heaving up of the stern would be great, inasmuch as, if a sea struck her on the quarter, she would not get away from it, simply because she could not travel, during the paying out, at more than six miles an hour; therefore, unless her brakes were very delicate, there must be a severe strain upon the cable. He thought, moreover, that the insulating medium employed was faulty. A microscopic examination of gutta percha showed it to be full of impurities. Those impurities, so long as they remained dry, were non-conductors, but the moment they became hydrous, they were conductors, and hence, he thought, the cable must, after a time, fail. There were, however, compounds such as paraffin, which could be obtained as pure as virgin wax, and the insulating qualities of which were superior to the purest indian rubber. It was, moreover, well known that paraffin was unalterable, that it was unpalatable to marine insects, and that it was exceedingly cheap. If they succeeded in laying this Atlantic cable, expensive as it was, the great demand that would be created for intelligence from across the Atlantic would stimulate others to prepare cables of a more suitable mechanical structure, and he had no doubt there would be four or five cables across the Atlantic within a comparatively short period. He therefore hoped that every judicious step for the success of the present enterprise would be taken by those in charge of it, for it would be a most unfortunate circumstance for the community at large if any mishap took place.

Capt. SELWYN said he had promised not to speak of his cylinder; but he had brought a model of it, in order to illustrate his theory of the curve taken by a submarine cable, as nearly as he could do so without the water. It was quite clear that with a rope or piece of twine he could not fully represent the resistance due to a body passing through water. He was therefore compelled to resort to a lighter and broader substance, consisting of the riband of paper, usually employed for printing telegrams, wound on to a reel, so as to give a certain per-centage of slack, but nothing like that given in laying out a cable in practice, and as the reel passed from one side of the room to the other, it would be seen that the curve described was an upward curve. There could be no better proof afforded that the resistance over a large surface of cable was something considerable, and that it could not follow, under these conditions, the inclined plane, the existence of which not only Mr. Siemens but other men highly placed in science, would have us believe. He (Capt. Selwyn) brought to bear on this subject his practical knowledge, extending over five-and-twenty years, in the use of ropes and in deep-sea soundings, and he had no hesitation in stating that the result of his experience was a belief in the curve which he had described. [The action of the model of Capt. Selwyn's cylinder was then exhibited by passing it several times across the room upon wires stretched as bearers, and the riband of paper

took the upward curve, as described. Capt. Selwyn then went on to remark that the chairman had informed him that the speed at which the model had travelled in this illustration was as near as possible six miles an hour, and thus it approached sufficiently near to the rate at which a cable was laid in practice. Mr. Siemens, in speaking of the curves, inferred that he (Capt. Selwyn) advocated the doing away with the retarding power over the cable. That was not so. The paddle-wheels of the cylinder were capable of exerting when necessary a very considerable retarding power; as long as the ship towed the cylinder a-head those brakes did not act, unless there was a pull upon the cable, which tended to produce a rotation of the cylinder in excess of the rate at which the ship was travelling, and that rotation was resisted by the beating of the paddles against the water. In point of fact he substituted water-brakes for the mechanical brakes, by which he believed no little mischief was occasioned to the cables that had been already laid. With regard to the precipices in the bed of the ocean referred to by Mr. Siemens, they were told, soon after the laying of the Atlantic cable, that there was a precipice on the shore of Ireland which led to the rupture there. In order to ascertain the matter, he went over the soundings with the late hydrographer, and he found the descent was only 1 in 16, being a little less than Holborn-hill. That there were such precipices as Mr. Siemens had described, in volcanic regions and on rocky coasts, there could be no doubt, but that was a warning to avoid such places in laying a cable, and by proper survey to ascertain that no such places existed along the path on which the cable was intended to be deposited. He had been much engaged in marine surveying, and he would say that any one employed in that work, who left unnoticed such a gulf as that described by Mr. Siemens, deserved much blame. Such a thing could not occur if the most ordinary care was exercised in surveying the ground before attempting to lay a cable upon it, and no engineer should be allowed to lay a cable where a surveyor had not preceded him to ascertain, with the utmost attainable accuracy, the form of the bed of the sea. With regard to the friction of the cable on these precipices (supposing it to have been laid on a badly selected route), he would point out that the heavier the cable was, the more mischief there was from friction; if it were not so heavy as to be incapable of being moved by the currents (a condition impossible of attainment in deep sea cables) then the weight was the most important element in producing damage by friction, having to be multiplied into the velocity of that friction. A cable of the specific gravity of gutta-percha, exposed to friction on a hard rock at the rate of 2,000 movements per minute, for a space of two feet, would last fifty times as long as one with an iron covering in the same situation. Here we had nature going before us. We had her anchoring her submarine vegetation to the stones and rocks in the bed of the sea, and allowing them to trail for long distances, and to be influenced by the ebb and flow of the tides. During that time they were subjected to great friction, but in no instance were they ever cut through, simply because they were not heavy, and the friction which would otherwise have destroyed them did not take place. On the shores of the Falkland Islands, and off Cape Horn, he had seen fuel (the *Juncus maritimus*) rising from a depth of 60 fathoms to the surface, with trunks as large as many of the oak trees met with in this country, and of such strength that ships which had dragged from their anchors had been saved by getting amongst the branches. They were made like the reed, which would bend to every storm, but more successfully resisted it than the oak. His friend Mr. Allan had happily found out that the making of a cable was so simple a matter that he was inclined to think the laying of it was an equally simple proceeding. On that point he was compelled to join issue with him; but he had no doubt when a cable of such

moderate specific gravity as Mr. Allan advocated was used, there would not be very much difficulty in laying it. There would be no kinks owing to the construction of the cable itself, and there would be much less difficulty in laying it than a spirally-covered cable. Dr. Bachhoffner had spoken of the resistance to friction, and he had already answered that point as far as he was able. With regard to the crystallisation of the conducting wires, that was known to electricians as the burning of the copper wires, and wherever, from the small area of the wire or the too great tension employed, the current was unduly retarded, this effect was produced. With a fine platinum wire the resistance was so great that it was brought to a white heat, and was destroyed under a current which would pass through a given area of large copper wire without resistance or heating. The coils used for magnetic purposes were liable to be heated if a current of too great tension were passed through them. It was a question how far the area of the conducting wires was diminished by mechanical violence below that which had been calculated by the electricians necessary to avoid such crystallisation as Dr. Bachhoffner had spoken of. With regard to paraffin, which Mr. Macintosh had alluded to, he (Capt. Selwyn) had, in company with more competent persons, closely tested the compound of paraffin and india rubber; and he believed the whole of what had been claimed for it was borne out, so far as the electrical conditions were concerned. The indestructibility of the compound could only as yet be inferred, but paraffin was in itself a substance which, as its name implied, had no affinities, and was not liable to the same process of decay as other substances having those affinities. Amongst those substances he gave the foremost place to iron wire, which oxydised under salt water with great rapidity, but hemp in contact with iron wire was destroyed even more rapidly. The use of tar only slightly retarded the decay. Where the spiral iron wires were surrounded by hemp, the destruction of the latter left them loose round the gutta percha; indeed the iron wire spiral was nothing more nor less than a most insidious enemy to the gutta percha and the copper conductor. Whether as regarded weight, producing friction on the bottom; whether as regarded the destruction of the hemp and the coincident oxydation of the iron wire, producing a number of sharp points which might destroy the gutta percha; or whether as regarded the expense, according to his views, the use of iron spiral coverings for deep sea submarine cables was wholly unjustifiable. He would rather see a simple gutta percha and copper wire cable than such an one. Though by no means saying that such would be the most perfect form, he believed there would be more chance for its durability in deep sea communication if the specific gravity were carefully studied. He was rather disappointed that the mathematical question involved in the curves had not met with a more able exponent than himself during the discussion. He conceived the curve was capable of being reduced to a true mathematical expression of the forces brought into play, and the Atlantic Telegraph Company might derive great benefit from those curves being ascertained before they proceeded with the laying of their cable. He hoped every precaution would be taken, for the interests at stake were very great, and upon the success of the enterprise depended the future of telegraphy, whether it should advance now or half a century hence, for if the present scheme broke down they might say good-bye to telegraphic communication with America, except through Russia, for a long time to come.

The CHAIRMAN said it was now his duty to ask the meeting to give a cordial vote of thanks to Capt. Selwyn for the very interesting paper he had favoured them with. A topic more worthy of discussion could hardly have been brought before them, considering the importance, both in a political and commercial point of view, of facilitating the communication with America. He agreed with Capt. Selwyn that if another £800,000 were lost, a third would

be forthcoming to try the experiment again. It was hardly possible, even if this next attempt failed, but that some further practical experience in these matters would have been gained by the failure, and even if another £800,000 was lost, the question of communication across the Atlantic was of such immense importance to the public that it was worth all this cost. When the commercial public were tired of the question, the governments must take it up. When all the science and all the great professional intellect of the country was being brought to bear on this subject, unless there were some at present unknown physical difficulties in the way, the time could not be far distant when an electric communication between America and England would be completed. Those who had taken part in this discussion had travelled a good deal away from the real subject brought before them, for Captain Selwyn did not open the question as to the merits of the different forms of cable. He (the chairman) thought it was to be regretted that some gentlemen present had expressed so strong an opinion on the merits of the cable now about to be tried under the auspices of eminent men, without having given notice that such a discussion was to arise, and without giving an opportunity for answering the statements so made. He was sorry that this *ex parte* discussion had taken place at a time when the public were looking to the completion of an enterprise fraught with such great results to the community. Nothing should be done to throw cold water upon the undertaking, but rather everything to encourage it. If it failed, those who had supported it would be the sufferers, and we should have to thank them for the experience gained, which might lead others, if not themselves, to a more successful result. There was one other point connected with this subject which he would just touch upon, that was the question of the survey of the bottom of the sea along the course where it was intended the cable should be laid. Many present, no doubt, recollected an occasion when some of the various surveys of the Channel were shown in that room. From them it appeared to have an almost perfectly level bottom; but he had heard it stated that much of this surveying was mere guess-work, and therefore that it was quite impossible, with such soundings, to say accurately what kind of surface was met with at the bottom of the ocean. Capt. Selwyn had, however, informed him that in the case of the Atlantic the soundings were complete and reliable for every ten miles of the whole route to America. If that were so they could hardly anticipate a casualty like that referred to by Mr. Siemens; but in the Mediterranean and other places the soundings might be only ten miles apart and yet there might be intervening rocks or precipices which would tend to injure the cable. He now called upon them to thank Capt. Selwyn for his admirable paper, and for the very lucid manner in which he had explained his views on this important subject.

The vote of thanks was then passed and acknowledged.

Proceedings of Institutions.

EXAMINATION OF SOLDIERS.—The following circular memorandum (Gen. No. 331), addressed to the army at home, has been issued:—"Miscellaneous 1 (1865).—The Field Marshal Commanding-in-Chief desires it to be notified that there will be no objection to soldiers, their wives, and families, being permitted to present themselves for instruction and examination at the Educational Institutes in connection with the Society of Arts, on the understanding that they are not on that account to be exempted from any military duty, nor, except in special cases, to be out of barracks after watch-setting or tattoo.—By command of his Royal Highness the Field Marshal Commanding-in-Chief, JAMES YORKE SCARLETT, Adj. Gen.—Horse Guards, S.W., 11th March, 1865."

NEWCASTLE-ON-TYNE MECHANICS' INSTITUTION.—On Wednesday, the 19th April, Sir George Grey laid the foundation stone of a new building for the Mechanics' Institution at Newcastle-on-Tyne. Several members of Parliament were present at the ceremony. In the evening a public meeting was held, over which Mr. Headlam, M.P., presided. An address of thanks was presented to Sir George Grey for his services at the ceremonial in the morning. Sir George Grey, in replying, referred to the origin of the society, now forty-one years ago. It was established in February, 1824; and its members felt pride in the names of those men under whose auspices it then was formed, and afterwards attained most distinguished eminence, and of which Newcastle and Northumberland were justly proud. To one in particular reference might be made—George Stephenson; and he was sure he only expressed the common wish of all who heard him when he said they earnestly desired that this one name might be handed down to successive generations of thousands worthy of the great man whose fame is identified with this part of the country, and who, amidst all his engrossing occupations and his world-wide fame, never lost the deep interest he took in this institution, because he believed it was calculated to confer inestimable benefits upon the class from which he sprang, and with which he never lost his connection. Another name he would also refer to—that of Lord Brougham, which could never be mentioned without honour in connection with Mechanics' Institutions, for which he had done so much, and in which he still retained the warm interest he ever felt in all that concerned the intellectual improvement of the people. Referring to the changes, political and commercial, which had taken place during the forty years since the institution was founded, Sir George Grey alluded to the repeal of the corn-laws, and the part taken by Mr. Cobden in this beneficial change. One of the greatest proofs of progress was the increase in the means of education. The means of carrying out the education of the working-classes was now extended to a degree which he believed the most sanguine friend of education forty years ago could not have anticipated. Education, however, was a life-long work, and consisted in availing oneself day by day, in the intercourse of ordinary life, of the means of increasing knowledge by reading, reflection, and intercourse with other men. And here it was that Mechanics' Institutes and libraries were found to be so valuable; there were few who had not some time to give to mental culture; but how many were there who had not the means of access to libraries and books from which to derive that instruction which they desired to obtain. Mechanics' Institutions and kindred associations placed within the reach of every individual man those means of education which, isolated and separated from the institution, he could not possibly obtain. In those Institutions a man might avail himself of that knowledge the means of acquiring which he had already obtained in the primary schools. These institutions gave a man an object worthier of his higher nature, and kept him from indulgence in those debasing pleasures which destroyed his domestic comfort, ruined his health, and too often ended in shame, misery, and crime. Would that these advantages were more generally appreciated. He trusted that, in this district, they were so. Referring to the recent differences between the masters and their workmen, he said he believed that the more the influences of these Mechanics' Institutions were extended, the more the means of knowledge conferred by these Institutions pervaded the mass of the people, the less chance would there be of those differences leading to consequences which all must deprecate.

DUBLIN INTERNATIONAL EXHIBITION.

The Exhibition was formally opened by His Royal Highness the Prince of Wales on Tuesday, the 9th inst. His Royal Highness arrived at about half-past two

o'clock, accompanied by the Duke of Cambridge, and attended by the Lord Lieutenant and Lady Wodehouse, Earl Spencer, and Sir Robert Peel, and was conducted to the dais which had been prepared for him.

The National Anthem having been performed, the Duke of Leinster read the following address:—

"To His Royal Highness Albert Edward, Prince of Wales, Earl of Dublin,—May it please your Royal Highness—For the distinguished honour of your Royal Highness's presence here this day, we, the Exhibition Committee, desire to offer our humble thanks. It is difficult for us to give expression to the feelings of joy and loyal satisfaction which fill the hearts of all who throng these halls to witness the inauguration of the Dublin International Exhibition of 1865 by your Royal Highness in the name of our beloved Sovereign. In this mark of favour and approval we discern not alone the Queen's high appreciation of the interests of industry and art, but especially her Majesty's gracious wish to promote the success of every enterprise which tends to advance the welfare of the Irish people. The act which your Royal Highness is about to perform cannot fail to remind us of the enlightened encouragement which the illustrious and lamented Prince Consort bestowed upon every work of usefulness, and especially upon undertakings like the present. International Exhibitions, bringing together the various nations of the earth, and making each better acquainted with the wants and with the resources of the rest, directly tend to stimulate industrial energy and increase commercial interchange, and, binding all people together by the ties of mutual interest, they become in no small degree the auxiliaries of peace and progress. The fine arts now occupy a prominent place in international exhibitions; the display of the best works of renowned artists opens up new sources of pleasure and delight, and forms a most important agent in the education of the people. We trust that the Exhibition at whose commencement your Royal Highness so graciously presides may prove not unproductive of such beneficial results, and that it may justify the hopes of those who, in honest labour and in self-reliant enterprise, recognise the true sources of national prosperity. We cannot conclude without expressing our heartfelt wishes for the health and happiness of your Royal Highness's illustrious consort, whom the Irish people earnestly desire to see amongst them. Whenever circumstances may permit her Royal Highness the Princess of Wales to visit our shores, which we trust will be at no distant period, we venture to promise such an enthusiastic welcome as will convey to her Majesty and to your Royal Highness the fullest assurance of loyalty and devotion."

To this address his Royal Highness was pleased to return the following reply:—

"My Lords and Gentlemen—I thank you for your address. It is a source of sincere pleasure to me to discharge the duty which has been confided to me by her Majesty the Queen in thus inaugurating your Exhibition. It is not less in accordance with my own feelings than with those of her Majesty to assist in every measure which is calculated for the happiness and welfare of the Irish people. The example of my lamented and beloved parent will, I trust, be ever present to my mind as a stimulus to the encouragement of every work which is calculated to advance international prosperity and to develop the resources of my country. The cultivation of the fine arts, in itself so powerful an auxiliary in civilising and refining the human race, has been an important object in this Exhibition, and seems already to have produced most satisfactory results. Believe me to be very sensible of your kind wishes on behalf of the Princess of Wales. Her regret at not being able to accompany me only equals my own; and you may rely on her anxiety to come among you assured of the welcome she will receive."

The Old Hundredth Psalm was then performed, and at its conclusion Mr. Gilbert Sanders, chairman of the

Exhibition Committee, read a report giving a history of the Exhibition Palace.

Mr. Parkinson (comptroller) presented to the Prince the key of the building. The Coronation Anthem was then sung, and at its conclusion an address was presented by the Lord Mayor of Dublin, to which his Royal Highness replied.

The "Heavens are Telling," from Haydn's *Creation*, was then performed, and at its conclusion the procession made the tour of the building. On the return of the Prince to the dais, the opening chorus from Mendelssohn's *Hymn of Praise* was performed. At its conclusion His Royal Highness commanded Sir Bernard Burke, Ulster King-at-Arms, to declare the Exhibition open.

SOCIETY OF ARTS PRIZE COTTAGES.

The following correspondence on this subject was prepared in the *Builder* of the 29th April and 6th May:—

The following is the result of a trial to get cottages built on the plan described in your number of the 31st of December, as having obtained the Society of Arts prize, and as estimated to cost £203 a pair.

The cottages to be built were six in number; the locality was Bishop's Stortford; and the very best means were taken to ensure that the plan and specification should be in strict accordance with the ideas of the designer.

Six tenders were obtained: three from London builders and three from the country. They were—

Perry, Stratford, London	£1,193 or £297	13	4	the pair
Bell and Sons, Cambridge	1,272 or	424	0	0
Glascock, Bishop's Stortford	1,380 or	460	0	0
Freeman and Sons, Ely	1,388 or	492	13	4
Patrick and Sons, London	1,392 or	464	0	0
Hill and Keddell, London	1,481 or	627	0	0

So that the lowest tender was nearly twice as much as the estimated cost of the prize cottage; the low estimated cost being, I presume, one of the principal grounds of awarding the prize to it.

Any one can build a good labourer's cottage: the difficulty is to build one for little money. I have had occasion to build hundreds, but could never build one that a decent family should live in under £140 or £150 a single cottage.

ROBERT SINCLAIR,
Engineer-in-Chief, Great Eastern Railway.

With reference to Mr. Sinclair's letter in the *Builder* of the 29th ult., I feel called upon, as the author of the design referred to, to state that the plans and specification upon which the estimates obtained by Mr. Sinclair were based, were, as indicated in his letter, prepared by me, and embodied not only the improvements and additions suggested by the judges in their report, but also such other improvements as had occurred to me since the preparation of the original design, in order to make them complete in every respect, without special regard to the estimated cost. It cannot therefore be expected that the estimated cost of the original design will bear a favourable comparison with the tenders obtained by Mr. Sinclair for the altered and improved plans and specification furnished to the company.

I may mention that, further than the preparation of the said plans and specification, I was not professionally employed, being quite unacquainted with the locality where the cottages were intended to be erected, and the nature of the site, and had not even heard the result of the tenders until observing Mr. Sinclair's letter.

Unquestionably the tenders obtained by Mr. Sinclair are high. Had a greater number of builders in the immediate neighbourhood, and in a much smaller way of business, been applied to, the result would, I have little doubt, have proved more satisfactory.

I have lately had occasion to obtain several estimates

from local builders for similar cottages which I am now erecting upon an estate on the borders of Kent and Surrey (about nine miles across country from the nearest railway station), the result of which I beg to subjoin:—

B. Ward, Warrington	£312	0	0	a pair.
Kesterton and Head, Lingfield	287	10	0	"
B. Bellchambers, Westerham	285	0	0	"
F. Shorter, Edenbridge	259	18	0	"
G. Crane, Cudham (accepted)	216	0	0	"

These estimates, however, were framed upon a plan and specification embracing the improvements suggested by the society, besides plastering and colouring to walls (not included in my original estimate), but with certain modifications in regard to the offices; i. e., dispensing with the w.c. apparatus, lead pipes, cistern, force-pump, and well, and substituting a rain-water tank, 5ft. diameter and 8ft. deep, with pumps, privies, and cesspool at end of garden, and including the cost of a piggery to each cottage, which, however, has been dispensed with in the tender accepted. Neither the timber for the roof nor the cartage of materials is included in the contract, the value of which, when added to the lowest estimate, will represent a sum close upon £260, the actual cost of the cottages per pair to the proprietor, bearing a favourable contrast with the average cost of good cottages, with similar conveniences, stated in the report of the judges previously referred to.

It will be observed that the locality where these cottages are being built is by no means easy of access; and it may be reasonably inferred, that under more favourable circumstances a considerable saving might be effected in the carriage of materials, an item of much importance in cottage building.

JOHN BIRCH.

ROYAL SCOTTISH SOCIETY OF ARTS.

The above Society proposes to award prizes of different values, of thirty sovereigns and under, in gold or silver medals, silver plate, or money, for approved communications primarily submitted to the Society by fellows or others, relative to inventions, discoveries, and improvements in the mechanical and chemical arts in general, and in their relation to the fine arts, and also to means by which the natural productions of the country may be made more available. The Society suggests the following as a few of the many subjects that may be attended to, viz:—

I. INVENTIONS, DISCOVERIES, OR IMPROVEMENTS IN THE USEFUL ARTS.

1. Mechanical Arts.

Inventions or improvements in applying the motive power of men and animals—in wind and water prime movers—in steam and other heat engines, including gas engines—in pumping, blowing, rolling, sawing, agricultural and other engines and machines—in cotton and other textile manufacturing mills—in ship-building, wood, iron, and steel—in lighthouses—in marine propellers—in railways, plant, and signals—in electro-magnetic motive power—in electric and other telegraphic apparatus, submarine and aerial—in photographic apparatus—in fire-proof buildings—in water-supply—in paving—sewerage—in economical appliances for increasing the sanitary condition of towns—in smoke consumption and extinguishing fires—in gas-works—in canals and inland navigation, including the application of steam-power to canal traffic—canal locks, inclines, and lifts—application of hydraulic power for lifts for domestic use—for cranes—printing presses—organ-blowing, and other similar purposes, where small propelling power is required—labour-saving machines for working in wood—in tools, implements, and apparatus for the various trades—in bricks, encaustic tiles, cements, and mortars—in printing machines, cases, and rollers—in stereotyping—in cranes—in the machinery for collieries—in preserving timber and

metals in marine works—in optical apparatus for astronomy, surveying, and levelling—in manufacture of paper—experiments on the effect of low temperatures on metals.

2. Chemical Arts.

Inventions or improvements in new and useful applications of gutta percha and vulcanised india rubber, or similar gums—in the economical extraction of chemical principles or useful substances, as paraffine, &c., from coal—porcelain clay from granite or felspar—and metals generally from their ores and oxides—in dyes—in paints—in paper—in glass, especially for lenses—in methods of rendering the electric light available in practice.

3. Relative to the Fine Arts.

Inventions or improvements in photographic processes, in "carbon" printing, and in methods of printing photographs from their impressions on steel or copper-plates, or lithographic stones—in electrotype processes—in die-sinking—in methods of illustrating books, to be printed with the letterpress—in paper-hangings—in articles of porcelain, common clay or metal—in glass-staining—in engraving on stone—in chromo-lithography—in "Nature" printing.

4. Natural Productions.

Discovery of plumbago mines—whetstones—of woods suitable for engraving.

II. Experiments applicable to the useful arts.

III. Communications of processes in the useful arts practised in this or other countries, but not generally known.

IV. Practical details of public or other undertakings of national importance, already executed, but not previously published; or valuable suggestions for originating such undertakings.

THE KEITH PRIZE, VALUE THIRTY SOVEREIGNS.

For some important "Invention, improvement, or discovery, in the useful arts, which shall be primarily submitted to the Society" during the session.

THE HEPBURN BIENNIAL PRIZE, VALUE ABOUT £12.

(If not awarded during Session 1864-65).

"For such inventions or communications submitted to the Society as shall be approved of by the Society, or by their Prize Committee."

THE MAKDOUGALL-BRISBANE BIENNIAL PRIZE, VALUE £10.

(If not awarded during Session 1864-65.)

"To the authors or inventors of communications of merit, which shall be approved of by the Society, or its committee, and judged by them deserving of such distinction."

THE REID AND AULD PRIZES.

For the first, second, and third best models of "Anything new in the art of clock and watch making—by journeymen or master watch and clock makers." If these should be considered worthy of prizes, the year's interest of the Reid and Auld bequest, being about seven guineas, divided among them in such proportions as the Prize Committee shall fix, according to merit. To such as deserve it, the Society may add to the amount of the prize out of its general funds.

By the liberality of Charles Cowan, Esq., of Logan-house, the president, and his partners, the Council are enabled to offer a prize of fifty sovereigns, with the Society's silver medal, for the best communication, if otherwise approved, on the "Purifying of Water which has been used in the manufacture of Paper."

The processes employed may shortly be stated to be:—

1. The washing of "filthy rags," and other fibrous materials, for which a large quantity of pure water is requisite.
2. The boiling of such materials in an alkaline solution, and the washing of the contents of the kiers or boilers in which the boiling operations have been conducted. And

3. The steeping of the half-stuff in chests in a solution of chloride of lime, and the washing of the partially exhausted bleaching agent from the half-stuff.

Intending competitors are requested to keep especially in view the circumstances in which the paper manufacture is carried on on the banks of the North Eek, in the county of Edinburgh. The merits of any suggestions which may be submitted will be regarded as being of greater value:—

1. By these being effected at moderate expense, and by their being applicable with as little interference as possible with the existing plant and mode of manufacture. And
2. By any substances, whether in suspension or solution, hitherto carried off in the stream, being demonstrated in practice, and by simple means to be capable of imparting fertility to arable or pasture land, or of being profitably applied otherwise.

Communications lodged in competition for prizes shall not have been patented, nor previously published, nor read before any other Society. Patented articles may, however, be exhibited and described.

For particulars as to the form in which communications should be sent, application should be made to John Beatson Bell, Esq., Secretary, 5, Hill-street, Edinburgh.

Manufactures.

RESPIRATORY APPARATUS.—Monsieur Galibert, of Paris, has invented an apparatus for affording a supply of atmospheric air to the lungs of persons working under water, or in places filled with noxious gases or smoke. The nose of the person is closed by a *pince-nez*, and a piece of horn or ivory, pierced with two holes, and shaped to some extent like the mouth, is inserted between the lips; adapted to each of these holes is a strong india rubber tube, capable of resisting pressure; these are fixed to the waist of the person, and then connected either with the outer air, if this can be arranged, or, if not, with an air-reservoir made of the entire skin of an animal, which may be carried on the back like a knapsack, and which contains a supply of air sufficient for a quarter or half an hour. The person using the apparatus should first apply the tongue to one hole and take a long inspiration, and then to the other hole during expiration. The apparatus, with air-reservoir, is intended to be employed by persons having occasion to remain some little time in wells, mines, drains, or in the midst of smoke. In some cases spectacles, specially calculated to protect the eyes, are added. When used under water, no air-reservoir is employed, but the tubes are made to communicate with the air. The inventor recommends its use for the purposes already referred to, as well as in cases where a total immersion of the body for some time in a bath is found desirable.

GREAT LENS.—A gigantic telescope is being made for the Imperial Observatory in Paris; and the great establishment of Saint Gobain has just completed for the new instrument a lens, of which the focal length is not given, but which is described as being seventy centimetres (28 inches) thick. It is six years since the lens was commenced, and it is said that the company presents it to the Observatory.

Commerce.

THE TEA DUTY.—Messrs. Capel and Co., in their circular, dated 8th May, say:—"We have had a fluctuating market since our last circular; the trade continued to buy freely at the improved rates quoted, until the morning of

the 17th ult., when an announcement in the *Times*, that a further reduction in the tea duties would form a feature of the Budget, led to more extensive purchases at a further advance of $\frac{1}{4}$ d. to 1d. per lb. When it became known that not only was this the case, but that the reduction was to the extent of 6d. per lb., there was considerable excitement, and on the Friday and Saturday offers to a large extent were made at prices showing a further rise of 1d. to $\frac{1}{4}$ d. per lb. The majority of holders, however, held out for still higher prices, and the business actually done was comparatively limited. Since then the excitement has subsided, and the prices now obtainable are only $\frac{1}{4}$ d. to 1d. per lb. above those of the 27th ult. The Government proposed that the reduction of duty should have taken place on the 6th instant, but the retail trade considered this a great hardship, owing to so short a notice after what they supposed to be a final settlement of the question in 1863; and, after great pressure, the Government have consented to postpone it until the 1st June. The postponement of the duty has also brought business to a partial stand, but when it comes fairly into operation we look to see a very large increase in consumption, as duty-paid tea will then be very cheap, and within the reach of a large portion of the population who have hitherto scarcely been consumers of the article."

Colonies.

PROPOSED DIVISION OF NEW ZEALAND.—In Auckland and Otago a movement for separation has sprung up. Auckland, shorn of its *prestige* as the capital city, and jealous of Wellington, demands to be constituted into a colony of itself, while Otago wishes to cut short the connection which exists between the northern and middle island. Auckland asks the Imperial Government to take the charge of native affairs, and pay the cost of doing so, while Otago wishes the north island in the future to bear alone the charges of the native war.

WELLINGTON CENSUS FOR 1865.—The total number of persons in the province, according to the present returns, appears to be 14,938, of whom 8,307 are males, and 6,631 females. In 1861 the total number was 12,565, thus showing an increase, during four years, of 2,373. The proportion between males and females is somewhat disturbed—the former being now more numerous. In 1861 the number of males was 6,626 against 5,940 females, while in 1865 the disproportion is greater. This in time may grow a serious evil, and demands a timely remedy in the shape of increased female immigration. The figures subjoined give some information as to the nationality of the population in the province. The English element is predominant, comprising one-third of the whole population; the Scotch rank next, but is much less prominent, being little more than one-tenth of the whole; while the Irish is still less. The remainder of the population are of New Zealand, Australian, Canadian, American, and European origin, those under the head of New Zealand figuring most largely in the returns. The advance in agricultural operations since 1861 has been very considerable; while in that year there were 55,313 acres under crop, the number now is 95,416 acres. The increase appears still more marked in going back farther still, the figures standing thus:—In 1855, 10,530 acres; in 1861, 55,313 acres, and in 1865, 95,416. The total number of acres fenced in is now 127,349. The increase in live stock has also been considerable. The present number of houses in the province is 2,900. The number of males in the province is 8,307; and of females, 6,631. The educational census shows that of those who cannot read (under 15 years of age) there are 3,173; above 15 years of age, 430; of those who can read (under 15 years of age), 1,064; above 15 years of age), 621; of those who can read and write (under 15 years of age, 2,258; above

15 years of age, 7,492. The number of acres under cultivation is 95,416.

NEW SOUTH WALES FINANCE.—At the opening of the Sydney Parliament, the Governor, referring to the finances of the state, said that during the year 1864 an additional deficit of £418,000 accrued, notwithstanding the many retrenchments made. The loss of crops from rust and inundations to the extent of at least half a million, and the loss of stock from disease and floods, by diminishing the purchasing power of the agriculturists, and other producers, very seriously cut down that portion of the revenue which is derived from customs' duties, while a great falling off in the sale of the waste lands of the Crown, deprived the Treasury of a large portion of the revenue ordinarily derivable from that source. He invited the members to look these financial difficulties in the face, and to aid the Government in providing the additional income, which was so urgently required to construct the public works, pay the debts, and maintain the credit of the colony.

COTTON AND SUGAR IN QUEENSLAND.—A local journal says that the failure of cotton cultivation in this colony may be attributed mainly to the absence of experience in its cultivation, a fatal belief having got possession of the public mind at the very outset that cotton would grow there without care or trouble. The contrary has been found to be the case, and it is now becoming a pretty general belief that no branch of cultivation requires more care or experience. The hopes of the colony as a cotton producer are now confined to the plantations of private individuals, most of the cotton companies having given it up. While, however, cotton, on the whole, has disappointed the planters, sugar cultivation has progressed in favour wherever tried during the last three years. Many agriculturists have planted quantities of cane during the past three or four seasons as an experiment, and the effect of severe droughts succeeded by floods for the last two years has convinced them that sugar cane is a certain crop and is offering every possible inducement for its cultivation. The fact has been well known that sugar-cane has thrived well in this colony during the last 15 years, but the absence of practical sugar manufacturers prevented any extent of cultivation until Captain Hope's enterprise in cane cultivation and the erection of sugar machinery at Cleveland, Moreton Bay, aroused public attention to the real value of its cultivation. The arrival in Queensland of a number of gentlemen from the West Indies, Mauritius, and other places, with a view of settling and investing their capital, has given confidence to capitalists desirous of investing in sugar plantations as a safe investment for colonial capital. Already upwards of 6,000 acres of land have been granted, under the Queensland sugar regulations, to gentlemen of high standing in this and other colonies.

Notes.

DISTRICT TELEGRAPH IN PARIS.—This service was established in January, 1864, and the cost of a minimum message was fixed at one franc. The number of messages was thus:—January, 577; February, 630; March, 745; April, 803; May, 808; June, 762; July, 784. On the 1st of August the cost of a message was reduced to half-franc, and the number of messages sent was as follows:—August, 2,500; September, 3,434; October, 6,849; November, 8,120.

PRESERVATION OF ICE IN SMALL QUANTITIES.—The importance of being able to keep small quantities of ice for various purposes, and especially in sick rooms for medical use, cannot be overrated. Dr. Schwarz has communicated the following simple method, which he has practised with success. He says, put the ice in a deep dish or jug, cover with a plate, and place the vessel on a pillow stuffed with feathers, and cover the top with another pillow carefully, by this means excluding the external air. Feathers

are well-known bad conductors of heat, and in consequence the ice is preserved from melting. Dr. Schwarz states that he has thus preserved six pounds of ice for eight days. The plan is simple, and within the reach of every household.

FRENCH ACADEMY OF MORAL AND POLITICAL SCIENCE.—Dr. Milman, Dean of Saint Paul's, has been elected a corresponding member in the historical section of this branch of the Institut of France, in place of M. De Raumer, recently raised to the rank of Foreign Associate.

CITY HORTICULTURE.—There will be an exhibition of floral decoration of balconies and windows, at the Royal Horticultural Gardens, on Her Majesty's birthday, May 24. Also, on the first Monday in August, will be awarded prizes for the best plants and vegetables cultivated by soldiers in barracks, by sailors in homes, by coast-guard men, and by workmen employed in her Majesty's dock-yards. Also at a public fête, on the first Monday in September, will be awarded prizes for specimens of window-gardening among the working classes in metropolitan parishes.

ROYAL HORTICULTURAL SOCIETY.—The last scientific meeting was held on May 2nd, when the Rev. M. J. Berkeley spoke on certain species of climatis, &c., and Mr. Bateman on orchids and vaccineæ.

SUBURBAN MUSEUMS.—On Saturday, the 6th inst., a meeting of gentlemen interested in the proposed establishment of metropolitan district museums of science and art was held at the South Kensington Museum. The meeting was convened by invitation of the Committee of Council on Education. Earl Granville presided, and among those present were Lord Ebury, Mr. Henry Cole, C.B., Secretary of the Science and Art Department, Lord H. Lennox, M.P., Mr. Ayrton, M.P., Mr. Beresford Hope, M.P., the Hon. Mr. Cowper, M.P., Mr. Locke, M.P., Mr. Bruce, M.P., Sir T. F. Buxton, M.P., Mr. Briscoe, M.P., Mr. Powell, M.P., Mr. Alderman Salomons, M.P., Mr. Tite, M.P., Mr. Harvey Lewis, M.P., &c. Earl Granville said the meeting had been called together merely for the purpose of discussing what should be done with the present iron building. When it was proposed to get rid of it a suggestion was made that, instead of selling it as old materials, it might be more usefully disposed of by presenting it, at a nominal price, to the different districts of the metropolis so as to form temporary local museums. He had very little doubt but that, when once these were established, the people of the several districts would soon make efforts to procure handsome buildings of their own. Considerable discussion took place, the opinion being expressed that district museums, particularly if kept open in the evening would be of great value to the working classes. It was explained that the Government proposed to accommodate three districts by dividing the building into three parts, a plan which received the approval of Mr. Tite, M.P., and others. A vote of thanks having been passed to Lord Granville, his lordship, in acknowledging the compliment, said the Science and Art Department were not by any means desirous of establishing a monopoly at South Kensington, but were most anxious to see district museums supported wherever they would be useful and agreeable to the inhabitants.

EDUCATION AND CRIME.—The large number of convicts at Toulon offers a good opportunity of noting the relation between cultivation and good conduct. It appears that there are at present 2,218 prisoners in the Bague of Toulon, of whom 1,330 can neither write nor read; 649 can barely do either; 208 read and write imperfectly; and only 31 possess superior education.

Correspondence.

TESTING AND WELDING BOILERS.—Sir,—In the very able paper of Mr. Paget, on steam boilers, he alludes to the various modes of testing their strength. With regard to the disadvantage of a pulsating action, I think there can

be no doubt, whether arising from the alternating action of the cylinders or from the strokes of a ram. The simple mode in the latter case to moderate the evil would be to use a ram with three strokes nearly neutralising each other; and the water should as nearly as possible be in the condition of heat induced by steam. If cold water be used approaching to frost, the metal will be rendered brittle and the joints leaky. With moderately-heated water the metal will be tougher and the joints tighter. As regards the general structure of boilers, it is radically vicious, and will continue to be so just as long as the principle of rivetting continues in use. No truth can be clearer than that the metal should be all of one equal thickness, at least where in contact with fire, and that thickness must not exceed the free action of heat in passing through it. If it be too thick, the metal will simply burn away till reduced to the right thickness, in those parts exposed to the fire, and thus the thickness will vary and the strains will be unequal. These conditions will limit the pressure that can be safely put on the boiler. In the application of heat to raise steam there can be no doubt that flame is the best method. We all know how rapidly a sheet of paper will boil water in a tea kettle, and therefore it is that, whenever we can get petroleum cheap enough and use it rightly it will be the best fuel, as it may be made to cover a larger surface with direct heat. But to do it perfectly we must have all the heating surface of equal thickness, a condition which cannot be attained till we get rid of the folded surfaces essential to rivetting. There is no apparent difficulty in welding all the seams of a boiler, whether of copper, iron, or steel. Welding is simply a condition of rendering the clean metal surfaces pasty, by heat, and then inducing perfect contact by pressure, uniting thoroughly the softened portions. That can only be done by the flame heat covering all portions of the surfaces to be united, without any uncombined oxygen getting access to them, for if it does, scaling will ensue; and when scale occurs the effect will be like that of dry flour between bakers' rolls—contact without union. Nor will either percussion or pressure drive out this scale, but on the contrary will drive it in. Now suppose two clean edges of a piece of welding metal to be placed an eighth or quarter of an inch apart from each other, and that they are held in position by a box of fire-clay, fitting close to all parts except those intended for union, with entrances and exits, or "gates," as technically termed by the founders, allowing a free passage of air through the joint; if then carburated hydrogen gas and atmospheric air, mixed in the right proportions for combustion, in a chamber under pressure, be forced through the joint, burning, the exposed surfaces of the joint will be made pasty or partially melted; and if pressure, hydraulic or other, be brought to bear to force them into contact, there will be homogeneous union without scale, because there will be no free oxygen to cause the scale, as in the ordinary mode, by irregular jets, and blows of a hammer; and there is no apparent reason why boilers, or any other weldings, should not be produced in the same manner, for the flow of the burning gas may be continued without intermission for any required time. My conviction is that this method will prove to be the true one for producing boilers without seams and rivets and of equalised thickness.—I am, &c.,

W. BRIDGES ADAMS.

THE WEAR AND TEAR OF STEAM BOILERS.—SIR,—Having read Mr. F. A. Paget's able and useful paper on "The Wear and Tear of Steam Boilers," published in your number for April 28th last, and in particular his account of the furrowing and pitting of boiler plates, I am glad to see that he gives what, in my opinion, are the true causes of these forms of destructive action. My object in now addressing you is to state that, in 1860, I published, at some length, my observations on this subject, in my work on the "Recent Practice in the Locomotive Engine," where I advanced precisely the same views of the causes of furrowing and pitting as those now

advocated by Mr. Paget; and, so far as I am aware, this was the earliest publication of the true causes. If I am in error, I shall be glad to be set right. Meantime, if you will allow me, I will shortly quote from "Recent Practice" my conclusions on the furrowing and pitting of boiler plates:—

"Probably the most important practical inference to be drawn from the tests of the strength of rivetted joints, is the explanation they supply of the failure, hitherto unexplained, of boiler plates, not at the joints, but in their neighbourhood. We are aware that electrical and galvanic action are freely introduced in explanation. But these words have two meanings:—they mean electricity and galvanism; and they mean ignorance and mystery. It is known that boilers fail by corrosion and other agencies eating into the plates on the inside, pitting and furrowing the surface. The pitting of the metal is readily explained by the presence of chemical agents in solution in the water, and the known inequality of substance of iron plates and bars, in consequence of which the metal is gradually but unequally separated and dissolved; and probably a weak galvanic circuit may be established between the iron and the brass tubes, accelerating the process of dissolution, but this explanation does not meet the frequent case of a straight continuous furrow, cut like a groove, upon the surface. Furrows are observed to be formed parallel to, and close to, the rivetted joints. Not in any case, that we are aware of, have they been found at any notable distance from a rivetted joint nor otherwise than parallel to one. The inference is inevitable that there is a relationship betwixt them; and our conclusion is, that the alternate tension and relaxation of the plates at the joints, as the steam is got up and let down, are attended by an alternate distortion, incontinent it may be, and resumption of the normal form, a bending and unbending of the plate on each side of the joint; in consequence of which the texture of the metal is gradually loosened in lines near to, and parallel to, the joint, and it is thus laid open to corrosive action. On this interpretation, the commencement of a groove or furrow, established at a weak place, and concentrating the action there, would tend to extend and deepen it to the dangerous limits occasionally announced by explosion. The weakness attendant on lap joints is strikingly exemplified in the lap welded joint when subjected to extreme tension: the tensile strength, though the metal weld is perfectly solid and fully as strong in itself as the base of the plate, is much below that due to the regular section of the plate. Here there is no elementary weakness in the reduction of metal by rivet-holes; the inferiority of strength arises solely from the bending of the plates on both sides of the lap, and the overstraining of the fire-box, in the endeavour to attain to the position of stability. . . . The furrowing of lap jointed plates reads an important lesson on the real and ultimately practical value of direct connection and direct action exerting, transmitting, or resisting forces. That the furrowing of plates at the rivetted joints results from the indirect strain of the steam pressure, is rendered still more probable by the analogous furrowing which results from reciprocating strains of another kind. In the more ancient class of engines, in which the cylinders are fixed to, and work from the smoke-box plates, the alternate forward and backward strains by the steam-pressure on the piston have been observed to weaken, and to subject to corrosion and leakage, the substance of the plate along the edge of the angle-iron at the junction with the barrel. In further corroboration of this doctrine, Mr. Colburn states that he is not aware that any accidents from furrowing of boiler plates have taken place in the United States; and we believe that their immunity from accidents arising from this source is to be ascribed to the use of rivetted boiler plates, quarter to five-sixteenths of an inch thick (Pages 15 and 16.)

In addition, my explanation of the destructive action of unequal expansion of the fire-box of locomotives and the shell, upon the stay bolts, in straining them laterally beyond the limits of elasticity, and thus permanently weakening them, was published at the same time; "Recent Practice," p. 16 and 17, and, I think, anticipated that Mr. Paget has just written on the same subject, that you can afford space for this letter, for in a paper like Mr. Paget's, elaborately based upon published authorities, it is of some importance, I think, that references, inadvertently incomplete, should be mentioned.—I am, &c.,

D. K. CLARK.

11, Adam-street, Adelphi, May 9th, 1865.

ON COLONIZATION; ITS ASPECTS AND RESULTS.—SIR,—It is late hour to which the discussion was protracted on evening of the 3rd inst., precluded my replying to one or two remarks of the speakers, and compel me reluctantly still further trespass on your space. The Chairman declined to think that I consider that mechanical conveniences tend to cheapen wages, whereas the contrary will be evident by reference to page 407, at the foot of the first and head of the second columns, where I give the rationale, as I conceive, of the increase in wages caused by machinery. Professor Levi drew attention to the fact that many persons emigrating to the United States in one year as contrasted with Canada. Two circumstances should be borne in mind in reference to this matter. Of the large number of fifty thousand emigrants, thirty-three thousand were Irish, the poorest class of emigrants; by the wealthier English, Australia, which is four times as expensive to reach, was preferred; and of the shrewd catch, while only 1,000 went to the States, 2,500 went to Canada, and upwards of 8,000 to Australia. We must, therefore, take into account the cheapness of getting to America, and the fact that the United States can scarcely be regarded as widely differing from our own country in its laws and habits, before we come to the conclusion that the nature of the Government has nothing to do with emigration. Almost as much money was sent from America as would pay the passage of all the emigrants. With reference to Mr. Torrens's remarks, I may observe that the English army is composed of some 150,000 men, of which 50,000 are kept in England, and 100,000 are distributed throughout our colonies and dependencies. The effect, therefore, of what bone and muscle may be necessary to maintain 100,000 efficient men abroad, a home country is exhausted; and as each man costs at £30 a-year, the money abstracted from the treasury on this account amounts to £3,000,000 annually. With respect to the colonies being represented in the House of Commons, I confess I once held the opinion of its expediency, but when I find how little even the importation of Indian labour can be made to interest the English Government, I must say I tremble for the attention which will be given to the proposed plan, be given to the hon. member for Vancouver's Island or Labuan. With reference to cotton, I have only to observe that if, in the hour of our need, we have drawn two-fifths of our supply from our own dependencies, that is a large proportion. Whether we can grow cotton to compete with America I am unable to say. It appears to me to be a question of climate, soil, seed, and treatment, and I should prefer seeing peaceful rivalry to any other condition of matters. I may add that it is not the South who have prevented us from growing cotton, but the North; and I believe I only echo the statement of every Englishman (from the Premier downwards) in severely reprobating the conduct of Butler. Mr. Hill somewhat hastily concluded that my views on transportation are theories. Twice I visited New South Wales in its convict days; twice I resided for some time at Van Dieman's Land; and it so chanced that I lived for 10 years with the only unofficial family who ever remained at Norfolk Island for any period while in its worst days. My opinions are based on personal observation. I have seen convicts and ticket men, in both New South Wales and Van Dieman's Land, whose cheques would be procured for thousands, whose acceptances would be discounted by the most scrupulous bank, who properly attended to all the duties of life, educating their children, sitting on juries side by side with freemen as fellow citizens, regularly attending divine service, &c. Now what do I see at home? Garotters, burglars of the most serious character; and almost every daily paper contains accounts of trials in which the worst class of offenders are stated to have previous convictions recorded against them. I cannot speak as to Ireland. I am only too happy to hear that Ireland is satisfied with her convicts; England certainly is not. Mr. Hill did not explain how he would act upon Bacon's dictum, and pre-

vent men "multiplying their depravity." It rather seems to me that the difference between us is mainly this—Mr. Hill would allow the race to propagate surrounded by their old vicious companions, and without room to grow out into purity; whereas I would allow them space and opportunity to return to obedience to the laws of nature and man. I am rather surprised that Mr. Hill should detect any similarity between the rock-bound, harbourless Norfolk Island, containing some fourteen square miles, with its masses of closely-huddled male convicts, and the Falkland Islands, containing some 7,000 square miles, with harbours and ports, where I proposed to disperse the convicts on small farms.—I am, &c., W. STONE.

MEETINGS FOR THE ENSUING WEEK.

- MON. British Architects, 8.
 Asiatic, 8.
 Royal United Service Inst., 8. Major C. H. Owen, R.A., "The Present State of the Artillery Question."
 TUES. Society of Arts, 8. Cantor Lectures. Dr. F. Crace Calvert, "On some of the Most Important Chemical Discoveries made within the last two years." (Lecture VI.)
 Civil Engineers, 8. Mr. Edward Fletcher, "On the Maintenance of Railway Rolling Stock."
 Statistical, 8. Prof. W. B. Jevons, M.A., "On the Variation of Prices and the Value of the Currency since 1782."

GRANTS OF PROVISIONAL PROTECTION.

- Abdominal and scrotal bandage—1016—A. Stewart.
 Bolders, apparatus for feeding—1062—R. A. Prooman.
 Boots and shoes, elastic binders for—1060—W. E. Newton.
 Boots and shoes, flexible spring waist for—1034—B. W. L. Nicoll.
 Buildings, apparatus for making communications from one part to another—1143—J. J. Parkes.
 Cigar cutter—1139—H. C. Butcher.
 Corn, &c., screening, sifting or riddling—1106—W. Beaven.
 Cues, rests or supports for—1048—G. Jackson.
 Dress, fastening for articles of—1165—C. W. Heaven.
 Distilling hydrocarbons, apparatus for—1076—J. Dougan.
 Electricity, communicating intelligence by means of—1088—R. A. Jones and J. Hedges.
 Engines, locomotive—48—C. de Bergue.
 Fabrics, securing buttons to—1151—G. Davies.
 Felts, &c., apparatus for printing—1156—J. Wilkinson, jun.
 Fibres, threads, &c., preparing—1169—R. A. Brooman.
 Fibrous materials, machinery for combing, &c.—1084—T. Whitehead and N. Nussey.
 Fibrous substances, preparing and spinning—1125—E. Lord.
 Fire-places and flues—989—E. Welch.
 Fire-arms—1046—T. J. Mayall.
 Fire-arms, breech-loading—1071—A. Henry.
 Fire-arms, breech-loading—1092—G. T. Bousfield.
 Glass, protecting designs on—1111—D. S. Buchanan.
 Hoop iron, manufacture of—4063—T. Bennett.
 Human hair, machinery for cutting—973—R. Maynard.
 India rubber, substitute for—1068—W. Clark.
 Iron, bar used in puddling—968—G. W. Dyson.
 Iron, manufacture of—1153—J. N. Brown and T. D. Clare.
 Iron safes and strong rooms—1054—J. Chubb.
 Lace or net fabric, articles of—1129—C. J. and J. A. Keenan.
 Ladies' skirts—1080—J. C. A. Henderson.
 Land, ploughing and tilling—1123—C. Hall.
 Liquids, pouring and decanting—1149—N. Sibily.
 Locomotive engines, &c., construction of—916—G. R. Stephenson and G. H. Phipps.
 Locomotives, compensating wheel to be used with—1022—J. J. Myers.

- Looms—1032—A. Turner.
 Looms—1070—M. Smith.
 Looms—1066—J. E. H. Andrew.
 Madder, treatment of—538—P. A. Le Comte de Fontaine-Moreau.
 Matches, receptacles for—1121—G. W., and J. Bettemann.
 Metallic rods, tapering the ends of—976—E. H. Newby.
 Metal plates, machine for straightening, bending, &c.—1082—J. Todd.
 Navigable balloons—930—P. Hasenlein.
 Oiling cans—1119—G. Whillock.
 Ores, &c., furnaces for smelting—942—H. Brook, J. Eastwood, and G. Brook, jun.
 Penholders—1147—W. E. Newton.
 Photographic cameras—1171—J. A. Rowland.
 Power engine—1062—H. Leonhardt.
 Pulley blocks, iron sheaves and bushes for—1085—J. Gardner, E. Lee, G. H. Wain, and S. C., and S. Hargrove.
 Pumps—1099—M. Housseplan.
 Railways, permanent way of—1131—W. Bunge.
 Railway trains, communication between the passengers and guard of—1078—G. W. Garrood.
 Railway trains, communication between the passengers and guard of—1097—J. Hancock and T. Evans.
 Railway trucks, &c., means of covering—1090—W. Riddell.
 Rotating brushes—1038—J. Haworth.
 Ships of war, &c., construction of—1107—H. Candwell.
 Ships, steering—1157—W. Elder.
 Solutions, apparatus employed in the concentration of—873—W. Walsh.
 Spindles, &c., apparatus for lubricating—1060—J. Rippon.
 Spinning, spools or bobbins to be used for—1127—J. H. Wilson.
 Steam boilers, safety apparatus for—1066—J. M. Courtauld.
 Suction and blast, method of applying—1028—R. A. Brooman.
 Superphosphates of lime, manufacture of soluble and assimilable—1181—W. Clark.
 Swimming, shoe for facilitating the art of—1145—A. Atkins.
 Tape or stop cocks—1101—W. Clark.
 Tubes, fitting of surface condensers—1133—A. V. Newton.
 Umbrella and parasol tip fasteners—833—R. Lubinski.
 Water and gas, pipes for conveying—1058—C. F. Cotterill.
 Waterproof fabrics, manufacture of—1159—J. C. Wickham and A. E. Deiss.
 Wet gas meters—1072—T. Newbigging and A. Hindle.
 Wheels—1024—S. Wright.
 Wood, taking impressions from the grain of—1117—W. Scarratt and W. Dean.
 Wool, treatment of—1042—H. Sikes and G. Jarmain.
 Wringing machines—922—H. Lewis.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

- Pumps—1210—C. E. Herpet.
 Silks, &c., apparatus for spinning—1202—F. A. Le Comte de Fontaine-Moreau.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MAY 24.—"On Anchors and Cables; their History, Varieties, and Properties." By THOMAS M. GLADSTONE, Esq., C.E.

MAY 31.—*Derby Day.* No Meeting.

JUNE 7.—*Extra Meeting.*—"On the Policy of an Amalgamation of the Railways of the United Kingdom, under Government Management." By WILLIAM HAWES, Esq., Chairman of the Council.

CONVERSAZIONE.

The Council have arranged for a *Conversazione* on Wednesday, the 14th June, at the South Kensington Museum, cards for which will shortly be issued.

INTERNATIONAL EXHIBITION OF 1862.—JURY REPORTS.

The Council beg leave to announce that there are a small number of copies remaining of these Reports, which may now be had on application at the Society's House, price £1 5s. in cloth, or £1 11s. 6d. bound in morocco.

Proceedings of the Society.

TWENTY-THIRD ORDINARY MEETING.

Wednesday, May 17th, 1865; M. Digby Wyatt, Esq., in the chair.

The following candidates were proposed for election as members of the Society:—

Roper-Curzon, Hon. Sidney, Grove House, Lower Tooting, S.

Scarell, Thomas, Beddgelert, Carnarvonshire.

The Paper read was—

THE MANUFACTURE OF ENCAUSTIC TILES AND CERAMIC ORNAMENTATION BY MACHINERY.

By ZERAH COLBURN, Esq., Memb. Inst. C.E.

Wherever the feet of primeval man fell often, whether in his dwelling, on the highway, such as it might have been, in the places of traffic, or in the rude temples of the earliest religion, he must have soon learned the necessity for paving. Once accustomed to pave, experience would soon teach him to choose the harder stones and well-baked earthen for the protection of his frequent paths, as well as for the preservation of the threshold and the hearth of his own home. In these uses of well-beaten and sun-dried clay, fictile art had its birth. The roughly-moulded forms employed for fire-places were soon found to harden with the heat; and, even before the vast brick-fields of Babel were worked, men might have said, "Let us make brick and burn them thoroughly." As a factitious stone the Romans made their bricks in the form of flags. At Toulouse the old Roman bricks are 14 inches long, 9 inches wide, and only 1½ inch thick, corresponding to our own notions of tiles—the word "tile" being believed to be from the Latin root of *tego*, to cover. Ages, however, before the conquest of Gaul, bricks of nearly the same proportions had been used for paving; and flooring, in brick and stone, at first roughly practised in obedience to necessity, at last became an art. The Greeks, with their fine taste for the beautiful in form and colour, appear to have been among the first to employ mosaic paving; and their own and Roman *tesseæ* of marbles and porphyritic stones—the colour sometimes altered by burning—still survive in nearly their original splendour. These were not confined merely to tessellated arrangements, nor to kaleidoscopic combinations of geometrical forms, but they often took a pictorial character, as in the Roman pavement at Cirencester; and modern artists have shown how indestructible mosaics of this class, made not of abaciscus, but of clay cubes, or dados, smaller than dice, may almost rival tapestries in their richness and blending of colour. The pavement at Cirencester, the ancient Corinthum, has, indeed, been adjudged by some of the first authorities in art to be a work of superior artistic merit. Its thirteen medallions, within as many compartments of guilloche bordering and decoration, are remarkable for the truth and precision of their figures, and they might almost be mistaken for paintings. In the late International Exhibition a mosaic pavement, by Messrs. Maw and Co., had upwards of eighty thousand *tesseæ*, mostly in quarter-inch cubes; and its five

medallions, from 1ft. 9in. to 2ft. 6in. in diameter, contained each a human head, almost living in its expression, and in which the flesh tints were graduated with remarkable accuracy, nearly rivaling the finish of portrait painting in oil. Messrs. Minton, Hollins and Co.'s mosaic pavements, exhibited on the same occasion, contained one hundred and fifty thousand cubes, of which eight thousand were included in a single classical head or medallion in the centre, and only ten inches in diameter. Although the ancients literally paved the way in the art of mosaic decoration in stone and terra cotta, we have already learned to excel the finest remains of this art in respect of elaborate design, and beauty, and careful graduation of colour; and more especially in mosaics formed wholly of natural stones, we possess a variety of materials, and an amount of skill in grouping and working them, sufficient to raise some of our productions to the level of the best examples of Florentine art. We can now command every variety of marble, whether monochromatic, variegated, or brecciated; and some of the recent mosaic pavements in the restored sacristy of certain of our cathedrals attest the value of the acquisition, to this branch of art, of the beautiful verde marbles from Connemara, near Galway. To the marbles we can bring serpentine from Mona and the Lizard, fluor spar from Derbyshire, red granite, steatite, lithographic stone, and even alabaster, aventurine, and malachite.

But mosaic decoration in natural stones must, if effective, always be costly. A recent beautiful stone mosaic, ten feet square, in the sacristy of Chichester Cathedral, cost £200, or £2 per square foot. And it is plain that mosaics in terra cotta, where elaborate arabesques and radiating or intertwining foliations are introduced—to say nothing of medallions—must be expensive also. Hence, at an early period, square tiles, curiously and richly ornamented, were employed for pavements and for walls. The decoration of the Alhambra, and of other works of the Moors while in Spain, largely consists of square tiles stamped with intricate and beautiful patterns. Many examples of this fine old Azulejo work, with the ornamental figures burnt in, or *encaustic*, in various coloured clays, are still to be found in very early structures; and in mediæval times encaustic tiles became comparatively common in church decoration. Instead of enamel, the encaustic tiles had their pattern impressed deeply into their upper or outer face, and the impression filled with one or more clays, which burnt to a different colour or colours from the body, thus leaving the pattern inlaid in the desired colour. Of course almost every tint and shade could be produced, both in the body and in the pattern, the clays in their natural state alone, without the mixture of pigments, giving a considerable range of colour. The manufacture was exceedingly simple, yet, whether from neglect, or from a change in popular taste, it had in later times become extinct; and in the beginning of the present century it might have been classed with the lost arts. There was enough, however, in the old encaustics themselves to show how they must have been made, at least, when they were carefully examined with the aid of moderate reflection and a little reasoning.

It was evident that encaustic tiles, while they admitted of a style of decoration not to be obtained in mosaic, could also be more cheaply produced, at least if the mosaic were in any considerable degree intricate; for to obtain an elaborate and varied pattern by mere tessellation, the tesserae must be very small—the smaller the better, until they approach in size the scarcely distinguishable squares in needle-work patterns in coloured wools. But, as each little cube has thus to be separately made and coloured—there being, perhaps, five hundred or a thousand of these in a space only six inches square—their manufacture would necessarily be slow, and therefore costly. In encaustic, on the contrary, the square of six inches—called a quarry, from the French *carre*—would be formed in a single piece; and, the impressing stamp once made, no matter

how intricate the design, hundreds or thousands of these quarries could be stamped successively, and filled in with the contrasting colour, with comparatively little labour. Ornamental tiles, it is true, are also cheaply made in majolica ware; but, however pleasing may be the forms pictured upon them, the surface of majolica is not so suitable, nor so satisfactory to the eye, as that of an unglazed tile, in its honesty of hardened clay and the genuine ingrain of its colouring.

It was in the year 1830 that the late Mr. Samuel Wright, then of Shelton, North Staffordshire, revived the manufacture of encaustic tiles, by specifying, under his patent of that date, his mode of making them. He employed a mould within an iron frame, and with a removable top and bottom, the inner surfaces of the mould being of plaster of Paris, which does not adhere to plastic clay. Once set, plaster of Paris is very hard, and hence Mr. Wright found no difficulty in forming in it the most intricately wrought designs, in alto relievo, for impressing the upper or outer surface of the tile.

It is now time to describe the manufacture of encaustic tiles as patented by Mr. Wright, from whom Messrs. Minton and Co. obtained a license, extended, by a prolongation of the patent by the Privy Council, to 1851. There are, no doubt, some gentlemen here who accompanied the Archaeological Association to Shrewsbury in 1860, and who then partook of the elegant hospitality of Mr. Maw, at Benthall-hall, near Broseley, and who there listened to a very succinct and interesting account, from that gentleman, of the whole process of encaustic tile-making. While referring to that account, the author gives the following, almost identical with it, but derived from his own observations in the potteries.

The stronger and purer clays and marls, from the coal measures, as also other clays brought from the South of England, burn, without the mixture of colouring matter, into red, buff, and fawn-coloured tiles; and, with the addition of different proportions of oxides of iron and manganese, they burn into the black, chocolate, and grey tiles. The higher qualities of tiles, such as the white and those of richer colour, are made from a kind of porcelain clay, or Parian, the white being left uncoloured, while the blues and greens are coloured with oxides of chrome and cobalt. Where the clay is too strong or adhesive, from a deficiency of silica, a greater or less proportion of sand is added for the coarser tiles; but for the finer qualities, the proper proportions of silica and alumina should exist in natural combination in the clay itself. The clay is all the better if “weathered” by exposure, in thin layers, to sunshine or to frost, the effect of both of which is to break it up into fine particles, and to secure increased waxiness, if the term is permissible, in working. The clays are then, and in mixture with whatever colouring matters are employed, reduced to a state which not only potters, but many others besides, know as “slap”; that is, they are mixed with water until the mixture becomes sloppy, and in this state they are strained through a sieve of fine lawn; the finer the better, and the finer often amounts to fifteen thousand meshes or perforations in the square inch. This process of sub-division, resembling filtration, although only the coarser matters are retained by the lawn, gives great fineness and evenness to the texture of the clay, while it adds also to the brilliancy of the colour. Thus strained, the viscous clay is then dried to a plastic state, upon what are called the slip kilns. It is as well to say at once that, even for plain tiles, or those of but a single colour, two qualities of clay are taken, one for the body of the tile, the other and finer sort for the upper, or perhaps, both the upper and the lower surfaces. As in much modern furniture, so in tiles, where the visible grain and colour are but superficial, the coating of the finer material is called *veneer*. The workman first fills the bottom of his plaster-mould with a thin layer of the finer or *veneer*ing clay, and then beats upon it the coarser or body clay, of which nearly seven-eighths of the whole thickness of the tile is formed.

dry clay he places a further coating of veneer on this he closes the mould. The bottom of the mould has raised upon it, in alto-relievo, the impressed pattern, and on reversing and he parts of the mould, and removing the tile, finding with its impressed design on its upper surface still plastic state, the impression upon the clay with a semi-liquid preparation of clay, of a quality which burns to the contrasting colour of the pattern. This "slip" not merely fills, but also the impression, and leaves the tile covered with a high coating, in which state it is taken to the kiln, and in perhaps forty-eight hours (often less) it is brought to the consistency of bees-wax. In this state of the tiles a workman, provided with a steel blade or scraper, proceeds to scrape down the surface of the tiles, removing the superfluous coating of overflowing "slip" and he continues this operation until he has brought the surface exactly down to the original surface of the pattern, bringing out the pattern sharply and distinctly. The tiles are then ready for the burning kiln. The burning is done in a kiln, about a week, half the time being occupied in raising the heat, and the other half in letting it down. This stage of the manufacture requires much care, as is indeed the case with all the goods of terra cotta and pottery. The goods are fired in a kiln, and the progress of the burning is judged of from the appearance of proof tiles, which are taken out with the charge, and successively withdrawn, until they are got up and let down. The shrinkage is not great, and tiles intended to be of the same size, when they were formed in the same mould, often shrink in their dimensions after burning that they will not hold in the same pavement. They are, therefore, gauged, and assorted into lots each of one

made are comparatively indestructible. A workman will hardly cut them, and considerable exposure to weather affects them but little. Ancient tiles are often sharp and apparently unchanged in colour, but the softness of strong texture has crumbled almost into powder. It is requisite, in order that the body clay of the tiles introduced into the pattern have equal strength as otherwise the pattern will not be firmly pressed into the body. Encaustic tiles made from well selected and properly burnt, will not, when broken in two, show any separation of the veneering from the body, or of the pattern from the veneering. In the case of a fracture across any joint between different tiles, the tiles will break off portions of both in each and every tile broken off.

From pugging the clay, and first drying and then burning the tile, the process of hand-moulding is a good one. A good workman will mould from one mould tiles, each six inches square, and in two days as an ordinary day's work. Plain tiles, or tiles of one colour, are moulded at the rate of only 750 tiles, each six inches square, per day, although very good workmen may turn out as many as 1,000. In the case of encaustic tiles it is estimated that the cost of labour only in moulding and trimming encaustic tiles is from 1s. 9d. to 2s. 6d. per tile, or from 6s. 3d. to 18s. per square yard, according to the intricacy of the patterns and the number of tiles moulded into them. This may be much cheaper than the expense is still sufficient to preclude the use of encaustic tiles in a vast number of cases, where, but for this, they would be most usefully and suitably employed. Where, on the one hand, the architect can afford the means requisite for the best class of ornamentation, he will naturally select the smaller and more elaborate *tesse*, arranging them in mosaics of some approved design; but where he is obliged to use encaustic tiles, the very considerable difference in the cost of the plainer and the more elaborate tiles will often induce him to employ the former to the exclusion of the latter. And where the choice lies only be-

tween tiles and oil cloth, the latter, although not nearly so durable, will commonly produce by far the best effect for the money.

It must have long ago occurred to many persons interested in constructive and decorative art, that to introduce encaustic tiles extensively it would be requisite that they were made by machinery. It is a singular thing that the art of working in clay—possibly the earliest of all the arts practised by man—should have been almost the last to derive advantage from mechanical ingenuity. Not but that there have been many attempts to employ machinery in brick-making; but even here it is but a few years, very few, indeed, since machine-made bricks were scarcely known. It is ten years only since the first step was taken towards the manufacture of encaustic tiles by machinery; the son of the late Mr. Samuel Wright, the inventor of the hand process already described, having, as a joint inventor, obtained his first patent in 1855. The encaustic tile machine, the joint invention of Mr. Samuel Barlow Wright and Mr. Henry Thomas Green, has been successively improved, until it now appears to have been perfected, and it is in successful use in the Potteries, although not to an extent commensurate with the importance of the new manufacture. The machine is very simple, and its general construction and mode of action may be easily understood from a verbal description and without illustrative drawings. At one end of the machine are three common pug mills, placed side by side in a row, in the direction of the length of the machine. The middle and larger mill is for pugging the coarser body clay, the other mills at the same time tempering the finer clay for the top and bottom veneering of the tile. The three pug mills discharge their clay in three continuous streams, between a pair of polished rollers, which compress; and, so to speak, weld the three streams into one. This is received upon, and carried forward by, an endless travelling table, or band, which extends horizontally for the whole length of the machine. As delivered upon this table, the compound stream of clay is of the intended thickness of the tile before burning, and of a little more than its intended width. It first passes under an impression roller, perhaps two feet in diameter, and around the circumference of which are fixed the plaster dies, corresponding to the intended encaustic pattern on the face of the tile. In the old or hand process the die is flat, and the face of the tile is formed by pressing the clay equally over its whole surface. In the machine the convexity of the die does not admit of a simultaneous impression of the entire pattern over the whole surface of the tile, the place of deepest impression, at any moment in the progress of the clay, being in a line across the width of the tile. But, notwithstanding this fact, and that the alto-relievo surface of the die (being one-eighth of an inch or so further than the bottom from the centre of the impression roller) moves forward about the one-hundredth part faster than the surface which presses upon the face of the tile, the impressions are nevertheless sharp, no matter how intricate the pattern may be. The impression-roller, as well as all the other working parts, must be driven so as to correspond exactly with the progress of the travelling table, or, in other words, with the progress of the advancing stream of clay. It will be understood that the impression-roller does not revolve by friction merely, as the clay is drawn under it, but that it is driven by gearing, at a definite speed, or, as mechanics would say, it has a positive motion. As soon as the continuous slab of clay has received the intended impression, it is cut into lengths corresponding to the intended size of the tile. This is effected by a guillotine wire cutter, which rises and falls at definite intervals, cutting the clay in its descent. Although the action of this cutter is only in a vertical direction, it is so arranged that, during the brief interval while it is passing through the clay, it shall move forward with it, returning again to its original position after the cut is completed.

Simple as all the parts, so far described, may

appear to be, everything depends upon absolute synchronism in their action. A greater amount of ingenuity, or, perhaps, it will be more truthful to say, of ingenious perseverance, has been devoted to this point than those unacquainted with the constant, but seldom recorded, skirmishes on the outposts of invention, would perhaps believe. Six years ago, my friend, Professor Hughes, or rather, his representative, Mr. Henry Hyde, described in this room his beautiful type-printing telegraphic instrument, to which, perhaps, we owe the introduction of the shilling telegram, which promises to become as general throughout Great Britain as the penny postage of Sir Rowland Hill. As in Messrs. Wright and Green's tile-making machine, so in Professor Hughes's telegraphic instruments, everything depends upon synchronous action, and this has been at last secured, beyond all doubt, in both inventions. In the tile-making machine the rate of progressive motion is about twelve feet per minute, corresponding to the moulding of twenty four 6-inch tiles per minute, or to 14,400 in ten hours, as compared with 200 or so moulded by hand in the same time. It is absolutely necessary that the pug mills deliver at the prescribed rate, that the polished compressing rollers move at that rate, and that the travelling table, the impression roller, and the guillotine cutter exactly conform to it. The rate may be 10, 12, or 20 feet per minute; but, whatever it is, all the parts of the machine must, as they do, work in perfect concord with each other.

After the advancing slab of clay has been cut into tiles, it passes under a reservoir or trough, of which indeed the procession of tiles forms the bottom, and within which the clay for the contrasting colour of the pattern is mixed with water to the consistency of "slip." The slip is filled into the impressions upon the tile, and overflows the whole surface of the tile to the depth of perhaps an eighth of an inch. The tiles are taken from the travelling table as they emerge from the end of the slip trough, and are conveyed thence to the drying kilns, where they remain until they are of the firmness of wax. They are then taken to a machine, consisting of a vertical spindle, in rapid revolution, and having one or more cutting blades fixed to its lower extremity, and revolving in a horizontal plane, as in one form of planing machine for planing wood. The tiles are placed, one by one, upon a horizontal bed-plate, which can be elevated or depressed through a small range beneath the revolving cutters, are rapidly surfaced, the overflowed slip being removed, and the pattern brought sharply out. This operation is almost instantaneous, and it leaves the tile with its two surfaces absolutely parallel with each other, and insures perfect equality of thickness in any number of tiles surfaced. Thence the tiles are squared to gauge upon the flat revolving side of a large grindstone, and, this operation being over, they are ready for burning.

The machine, with two or three attendants, does the work of from sixty to a hundred hand moulders. It works the clay more uniformly into goods than can be done by hand, and the slip pattern is deposited with more uniform density and with less risk of imprisoned air, so that the pattern burns better, and is still less likely than in hand-made goods to crack out from the body of the tile. Nothing, it is believed, can exceed the soundness and truth of the machine made tiles here upon the table; the patterns being as integral with the veneering, and the veneering with the body, as if the various clays had been actually incorporated together into one homogeneous mass. On the other hand, although the machine can make tiles with most intricate and delicate designs, even to the filiform tracery or tendrill like stalks of the most curious arabesques, it can only make bicoloured tiles, as the details of the pattern can only be filled from one and the same trough of slip clay.

Another, and possibly a still more important purpose of the machine is that of making both intaglio and relievé ornaments upon slabs of plastic clay, to be burnt into terra cotta decoration for walls. In this way cheap

and most durable friezes and dados, enriched ante, and other work, whether anaglyphic or sunk, and, indeed, ornate slabs for covering the entire *façades* of buildings, may—if we disregard the extra cost of the finer clay required—be made almost as cheaply as bricks themselves. No matter how enriched may be the design, these slabs, of which we have samples here, may be produced by one machine at the rate of 5,000 square feet per day, equal to the encasing of a *façade*, allowing one half its surface for windows, of 200 feet long and 50 feet high. Such ornamentation, produced by hand moulding, has been more or less employed for a long time, but it is costly in the first place, and it is commonly made of a close-grained clay, which does not withstand the weather as it ought. By the aid of machinery, with its increased power of compression and consolidation, a more open and durable quality of clay—that is one having more silica—may be employed; and at the same time still larger slabs may be produced. The known cost of production is so low that it may be at once declared that such slabs may be sold at a cost below that of rough stone, at the quarry or without labour, the plainer slabs being sold at 6d. per superficial foot, and the enriched patterns, which are made with almost the same facility, at from 9d. to 1s. 6d. Ordinary bricks are now made by machinery, with projecting dovetail, and these bricks may be built into walls so as to project from two inches to two and a half. The terra cotta slabs are formed with corresponding grooves. When the brickwork is raised to the height of one course of blocks, these are affixed, and the joints run with cement grout; and the *façade* of slabs is secured in successive courses in the same manner until the whole is complete. In this way a building of a richly ornamented character could be erected in less time, and at as little cost, as the present unsightly structures in brick.

It may be that enough has been already said of the commercial advantages of the new manufacture. For more might, however, be added. In the presence of a practical an assembly as this, it may be as well to enable those who are disposed to check every statement of the cost of production, to do so with the light already derived from experience in working the new machine in the Potteries. For a production of 12,000 6-inch tiles per day, or 2,000 square yards of tiles per week, about 7½ tons of body clay and 48 tons of slip or veneering clay would be required weekly. In certain localities, furnishing the required qualities, the coarser clay can be raised and moved for 3s. 6d. per ton, and the finer for 7s. 6d. per ton, including royalties, making £80 12s. weekly for clay. The coloured slips might cost £10 more. The wages of men and boys at the machine are taken at £6 1s. per week, and the cost of labour in facing and edging tiles as £25. The cost of setting, burning, and drawing the tiles may be set down as £18 more per week. The cost for drying and burning, and for the engine, may be taken as £20; the cost for warehousing, sorting, and packing as £10 per week; wages of engine-driver and fireman as £1; and wear and tear, oil and grease as £5. The cost of management, clerks, and designs would be, say £21 per week; rates and taxes, £1 6s.; commission on sales (£450 weekly at £10 per cent.), £45; stationery and advertisements, for the first year, £22; loss and contingencies, supposing them to be £20 per cent. upon the whole sales, £90; and interest on capital expended, say £30. This makes in all, £337 12s., or say £16,800 per annum. The sales, on the other hand, at 2,000 square yards weekly, for 50 weeks in the year, at the low price of 4s. 6d. per square yard, which is less than the cost of labour alone in making hand-made tiles of equal quality, would amount to £22,500, leaving £5,700 profit, or about 22½ per cent. profit upon a fixed investment of £25,000, in itself ample for the working of a single machine. The profits upon an additional investment to the same extent, in the department of terra cotta or ceramic decoration, making 30,000 square feet weekly, to be sold at 6d. per foot, would, upon the ordinary experience of

pottery, be quite as great. These details, the result of careful inquiry and of accumulated experience, are given rather to show the advantages in cheapness and in the character of work obtainable in the new manufacture. The architect—as are nearly all who are engaged in the arts of construction—is more or less bound in his designs by commercial considerations; and to give him a known material at a cost commercially within the limits of general application, where previously it could only be sparingly employed, is virtually to give him a new material.

DISCUSSION.

Mr. GARLING said he had been much interested by the paper that had been brought before them. The whole operation described appeared to be a very practical one; and the details given with regard to cost and to the working of the machinery tended to give him a favourable impression of the invention. These tiles afforded a pleasing form of architectural ornamentation, and any means of cheapening their manufacture could not fail to enlist the sympathies of all interested in the progress of art. The machinery by which this object was accomplished, the particular kind of material used, and the design applied to it, were all important elements in this production, and on all these points the statements of Mr. Colburn appeared to be very satisfactory. He was not aware that any observations he could make would render more clear the explanation already given, because he thought each branch of the process had been described in sufficient detail. The designs shown were very beautiful, and the cost of production by machinery was not only a great deal less, but the results were superior to anything that could be produced by manual labour, and as these tiles would thus be made in larger quantities than formerly they would be more available to the architect and the builder.

Mr. SPENCER GARRETT had listened with great pleasure to a paper on a manufacture with which he had been connected for many years past. He had heard of this machinery from its first introduction, and it had afforded him much pleasure to be informed, from time to time, of its progress. He regarded it as a great discovery, and the condition to which it had arrived was, in his opinion, only the first-fruits of what might be looked for hereafter. The improvements still to be made were, doubtless, very considerable. He ventured to make this statement as a practical potter, and he would be only too happy to aid the progress of this manufacture by all the means in his power.

The CHAIRMAN would be glad to hear from Mr. Colburn the process by which the pattern originally made that was brought into a circular form and applied to the cylinder.

Mr. COLBURN replied that the pattern was formed by a circular mould.

Mr. BISHOP said he had been much interested in the examination of tessellated pavements in Egypt, especially those in a mosque near Cairo. The pattern on the tiles appeared to have been produced by a stencil plate, and the glaze poured or brushed on afterwards, and then burnt in. The pattern was not indented in the tile, as was the case at the Alhambra, where he was struck with the great variety of geometrical patterns that were formed, which were of a much more distinct character of outline than those produced by the stencil. He had also seen a very beautiful description of tile in houses at Ta'giere, which was evidently of the same manufacture as those used in Spain.

The CHAIRMAN remarked that there were many interesting branches of this manufacture. There was a class of tile which was ornamented by the mixture of simple glazes, and another class which was ornamented by the application of vitreous colours, which were more brilliant than the natural glazes, and altered the character of the tiles entirely. There was a class of tile in use in

India which consisted of a combination of both these modes of ornamentation; in these the pattern was first formed by the ordinary red and white glazes, and then the whole tile was floated over with a glaze which gave it another colour. Some very beautiful specimens of tiles were brought over by the late Lord Canning, and were now to be seen in the Indian Museum. The patterns on these tiles appeared to have been produced by stencilling, except in some cases where the process which was common in the Norman tiles of the north of France was employed. A star or other ornament was made in a piece of clay of one colour, and the enclosing frame, completing the square of the tile, in clay of another colour. These were then interchanged in the same manner as in marquetrie work.

A question having been asked whether these tiles could only be made in two colours by the machinery,

Mr. COLBURN replied that at present that was the limit of the applicability of the machine; and, as far as he at present knew, was likely to remain so.

Mr. MATTHEWS added that he regarded the variety of colour as a very important point. As a young architect, desirous of using these tiles for exterior decoration, he was very anxious to hear what the probabilities of the future were with regard to the production of varieties of colour, the absence of which, he apprehended, would much limit the use of these materials.

Mr. COLBURN did not see how with the present machinery more than two colours could be introduced. The whole slab of clay passed under the trough, and, in fact, formed the bottom of the trough containing the slip or thin clay which gave the colour of the pattern.

The CHAIRMAN said that, in this manufacture, the application of improved machinery to the tempering of the clay would be a great advantage. At present the methods of preparing the clay for ceramic manufacture were somewhat barbarous, and he thought might be materially improved.

Mr. GARRETT added that the process of printing paper hangings in several different colours by one machine, had furnished him with some ideas in respect of introducing varieties of colour into this manufacture.

Capt. SYMONDS, R.N., might state, in the absence of the inventors of this machine, that he had seen it in full working, and its operations were minutely explained to him. The great point which was effected by the application of this machinery appeared to be the quantity of tiles delivered in a given time, and the consequent saving as compared with hand labour. He believed he was justified in saying it was in contemplation to carry out the suggestion of introducing more than one colour into the tiles. The inventors, as might be supposed, had many difficulties to overcome in producing the specimens now shown, but they were by no means discouraged from attempting to realise higher results.

The CHAIRMAN said one of the great difficulties at present with respect to tile-making in more than two colours was now overcome by hand-labour. For instance, let them call the original colour No. 1, and the second colour No. 2. If No. 1 made a complete form, it was easy to put in No. 2 by machinery; but supposing the pattern required that No. 2 should be put in, in immediate contact with No. 1, it was obvious that No. 2 could not be put in till No. 1 had become sufficiently hard not to mix with it. That was the difficulty of getting a second pattern into the tile. As the machinery was at present constructed, the slip which formed the second colour covered the tile, and no means had yet been suggested of introducing a third colour.

Capt. SYMONDS remarked that, allowing this difficulty, there was still great advantage in manufacturing tiles by this machinery, for even if a greater variety of colour involved a subsequent manual operation, there would still be a considerable margin in cost of production in favour of the machine.

The CHAIRMAN said that no doubt this would be so. He

added, that before the discussion closed he thought it desirable to direct attention to another application of this machinery, namely, the production of ornamented slabs with indented surfaces. These would form an admirable facing for exterior walls, and be a good substitute for the Portland and Roman cement now employed.

After a conversation relative to the cost of producing the moulds,

The CHAIRMAN said he would now offer a few general observations upon what struck him as the most important points in the paper. In the first place, they might clearly recognise the improvements now effected in the manufacture of tiles, as analogous to those produced by cylinder as compared with block printing; and the modifications which were thus being effected in ceramic manufactures were of the same character as those which cylinder printing had introduced in the ornamentation of textile fabrics. To say that the result of the application of machinery to this particular branch of manufacture had been to economise the production of it to the extent of 4 to 1, was, he believed, a moderate estimate. Of course, in calico-printing, paper-staining, and also in chromo-lithography, the operation of giving the required number of colours was comparatively easy, because each cylinder as it passed did its work immediately. The great difficulty in this case was to bring the slip into such a consistency as that it could receive and retain an impression from succeeding cylinders. The only way, he apprehended, of introducing a second colour of pattern would be, after the first slip was passed over, to remove the tile to the kiln till the slip acquired a consistency which would enable it to retain a second impression, and then to place it again in the machine. Even then it would be necessary so to arrange the pattern as to make the first impression include the second colour. When the filling-in was got into a plastic state that would again be brought to the second cylinder, and, a proper register being preserved, the tile would receive a second impression, and then the second process of pouring in the slip would supply an additional colour. It was easy to do this by hand-work, but difficult by machinery, but this appeared to him a means of getting over the principal difficulty which hung over this manufacture by machinery. With regard to the wall facing slabs to which he had called attention, the main difficulty was their safe attachment to the wall. The material was heavy, and if frost attacked the mortar behind the slab, and it became detached, there would be great danger to passengers in the street. There must be some mechanical attachment other than that which could be provided by projections on the edges of the bricks it was to be attached to, with corresponding indentations in the back of the slab. The great difficulty in this plan was to properly fit the work. The desideratum was to provide a mechanical means of attachment which should allow this facing material to be used anywhere. Having described a patent which he took out for this purpose some years ago, but which he said had lapsed from not having been brought into use, owing perhaps to public taste not having then gone in the direction of this kind of ornamentation, the chairman suggested that some ingenious individual might probably be able to make some use of it in connection with these revived methods of architectural decoration. He then went on to remark that, apart from the consideration of the improvement effected in the manufacture of tiles, they must admire the extreme ingenuity of the machinery itself. The synchronous action of the machine in all its parts was essential, but this to a mechanical mind such as Mr. Colburn's was no difficulty at all. All who designed machinery upon systematic principles, took care to bear in mind not only the motion to be made but also the time in which that motion should be made. By means of a diagram on the board, of the cylinder used in the tile-making machine, the Chairman pointed out a method by which he conceived the difficulties mentioned

in respect of the synchronism of motion in the machine might be obviated; after which he remarked that there was another aspect in which this manufacture was most important, that was, in relation to its influence upon architecture and beauty. It was important, in choosing the colours to be employed, to avoid making the contrasts crude and violent when to be seen near to the eye, though, of course, when things were seen at a distance the contrasts might be made more striking. When we had this ready means of chromatic decoration, it behoved us not to abuse it or use it wrongly, but to take care that it was directed by true principles of art. The chairman concluded by proposing a vote of thanks to Mr. Colburn for his excellent paper, which having been cordially adopted,

MR. COLBURN expressed his gratification at the kind way in which his paper had been received, and his personal obligations to the Chairman for the able manner in which he had summed up the subject. Speaking from an architectural point of view, no doubt if encaustic tiles had been the fashion fifty years ago, machinery would have been provided to make them, but their general introduction, as was well known, had been quite recent, and it was only very lately that ingenuity had been directed to their production by machinery. The practical result they had arrived at was, that if this description of tile was wanted in large quantities, it could now be produced at such a low price that nothing made by hand-labour could compete with it.

Proceedings of Institutions.

CROYDON LITERARY AND SCIENTIFIC INSTITUTION.—The report for last year states that the directors have become the actual lessees of the building, in which hitherto the Institution has only been a yearly tenant. The balance sheet shows that the income was £1,088 17s. 10d., and that there was a balance in the hands of the treasurer of £90 18s. 11d. The following are the numbers of members enrolled during the year:—First quarter, 88; second quarter, 796; third quarter, 717; fourth quarter, 544; quarterly average, 728. In comparison with the former year, there is a decrease of forty members, and £80 less in receipts from members. There was a large addition of life members, no less than 84 having been qualified as first-class members, and four as second-class. The summer fête resulted in a profit of about £7; upwards of 2,000 attended on the occasion. 292 volumes have been added to the library during the year; 269 volumes were purchased at an expense of £46 4s. 8d. in funds of the Institution, and 48 were presented. The total issue of books for the year was, 9,312. Thirty lectures and entertainments were given during the year, with an average attendance of 501. Amongst these may be mentioned:—Mr. Henry Vincent, on "Oliver Cromwell; Captain James Ricket (of Cooterstock), "The Sea Ships, Sailors, &c.;" Dr. Daniel, "Lord Nelson;" Rev. A. B. Power, on "Heat;" Rev. J. M. Bellew, "Milton;" Professor Selwyn (of Cambridge), "The Sun;" Professor R. Hunt, on "Electrical Force;" Dr. Letheby, "Oxygen Gas;" Mrs. C. L. Balfour, "Lady M. W. Montagu;" Rev. J. M. Bellew, "Shakespeare;" Mr. Elihu Burritt, "The Physiology of Nations;" Mr. George Dawson, "Great Schoolmasters;" Rev. J. B. Owen (of Chelsea), "Cliques." Several were given gratuitously. The Committee mention with regret that Mr. F. Warren has announced his intention of retiring from the hon. secretaryship at the end of the present year. Mr. Warren has been the mainstay and the life of the Institution, and at the urgent solicitation of the Committee, he has reluctantly consented to continue his valuable services for another year.

YORKSHIRE UNION OF MECHANICS' INSTITUTES.—The annual meeting will be held at Stockton-on-Tees on

Thursday, 8th June, in Whitsun-week. In the forenoon the conference of delegates will be held in the Borough-hall, when Mr. Edward Baines, M.P., the president of the union, will take the chair. The report of the Central Committee will be presented, and several interesting questions will be submitted for discussion. In the afternoon the delegates and other visitors will dine together at the Black Lion Hotel; and in the evening a public meeting will be held in the Borough-hall, at which the Right Hon. Thomas Headlam, M.P., Judge Advocate-General, will preside. On the Friday the delegates will have an opportunity of visiting the extensive iron ship-building yards in the neighbourhood, after which they will be conveyed by special train to Gisborough, to see the ironstone mines whence are derived the great mineral treasures of the Cleveland district; and the beautiful and picturesque seat of the Earl of Zetland, at Upleatham. They will then proceed to Saltburn, the new watering-place on the North-Eastern coast, where luncheon will be provided.

Fine Arts.

PARIS EXHIBITION OF FINE ARTS.—This exhibition was opened on the 1st day of May, as usual, without any previous private view. The Emperor visited it just before leaving for Algeria. It is fortunate that Paris possesses such a building as the *Palais de l'Industrie*, otherwise it would be very difficult to find a place for these annual exhibitions, which are assuming colossal proportions. Last year the total number of works admitted by the jury, and exempt from previous examination, amounted to 8006, including all classes—paintings, drawings, miniatures, enamels, sculpture, architecture, engraving, and lithography. This year the total is 3,559, although certainly the admission jury has not been more lenient upon the present than it was on the last occasion. The exhibition in separate rooms of such of the rejected works as their authors chose to leave for that purpose has not been repeated. Last year there were 1,150 pictures refused, two-thirds of which were immediately withdrawn by their authors, and the exhibition of the rest had such an effect that no one desired a repetition of the show. The rewards consist of two grand medals of honour, each of 4,000 francs value, forty medals, of the value of 400 francs each, in the section of painting, fifteen in that of sculpture and die sinking, six in architecture, and eight in engraving and lithography. In addition the jury has the privilege of recommending for the Legion of Honour any artist who may have received one of these medals on two occasions. All the medals are awarded before the opening of the exposition, and labels inform the public not only which works or which artists have obtained prizes, but also whether they were admitted by right, the artist having previously received certain distinctions or after examination by the jury; or whether they were *hors de concours*, in consequence of the artist being a member of the jury. The grand medals of honour have been bestowed upon M. Cabanel for painting, and M. Paul Dubois in sculpture. M. Cabanel's reputation is well established; he is one of the professors of the new governmental school of the Beaux Arts, a member of the *Institut*, and the painter of many works known by their photographs all over Europe. Amongst these, perhaps, the beautiful oval, *Aglæe et Boniface*, is the purest and most remarkable. M. Cabanel has only two portraits in the exhibition, but one is of the Emperor, who is painted in plain dress. M. Cabanel's is a very remarkable work, curiously unlike that of Flandrin in almost every respect; he has softened the features of Louis Napoleon, but he has shown more of the intellectual character than his predecessor. As regards technical execution this portrait is excellent. The other portrait is that of a lady in a purple velvet dress, a most refined and exquisite work. M. Paul

Dubois, to whom the other grand medal of honour has been awarded, is a much younger man, who obtained a third class medal for sculpture in 1863, but failed to obtain any reward last year; the work which has thus been crowned is very charming. It is a statue of a Florentine youth, in the costume of the 15th century, singing to his own accompaniment on the lute. The face is full of serious energy, and the half-developed muscles of the youthful form exhibit intense study and most delicate handling. M. Dubois, like the great sculptors of old, does not confine himself to one phase of his art, but exhibits this year, as he did last, also in the section of drawings and sketches. He is a native of Nogent-sur-Seine and pupil of M. Toussaint, but not a laureate of the Academy. The works belonging to the class of painting are no less than 2,248 in number, against 1,995 last year. Two circumstances, amongst others, have contributed to alter, to some extent, the general character of the exhibition. In the first place, the absence of war, and the surfeit which the public has had of huge flashy battle pieces, have at once lessened the number of such works and greatly improved the remainder. The most remarkable battle piece in the Exhibition, a "Charge of Artillery," by M. Adolphe Schreyer, a young artist of Frankfurt, (only known in the Paris world as having obtained a medal last year for a landscape with horses, which has been purchased by the government, after having been rewarded with a medal by the jury) is a simple, bold, serious work of high character. The whole main plan of the picture, which is large, is occupied by a gun, drawn by six horses with two artillerymen on horseback. The soldier who rides the near wheeler is wounded and falling back in his saddle, the horse has become entangled in the harness, and hangs back, while the others in full gallop drag it along. M. Pils, who gained the grand medal for his picture of the French part in the battle of the Alma, in 1861, and who is now one of the Professors of the Ecole des Beaux Arts, introduced, or at any rate confirmed, this new and wholesome mode of dealing with military subjects, which is adopted by Bellangé, Protais, and other eminent French artists. Of the other Professors of the School of Fine Arts, M. Robert Fleury, the director, does not exhibit, but M. Gérôme contributes two works—one, a picture, painted by command, of the reception of the Siamese embassy by the Emperor at Fontainebleau. The Siamese are on all fours in the centre of the room, with the exception of the chief ambassador, who has reached the foot of the throne and presents his master's letter to the Emperor. The magnificent presents are on the steps of the throne, and there is a group of ladies behind the Empress. M. Gérôme's other work, "Mussulmen praying on the house tops," is an effective picture. Amongst the most prominent works, besides those already mentioned, are two pictures in mediæval style by M. Alma Tadema, a pupil of Mr. Leys, of Holland; "Youth," by Aubert; "A Diana," by Baudry, who, however, has not achieved a great success this year; "The charge of the French cuirassiers at Waterloo," after Victor Hugo, by Bellangé; "Twelfth day in Alsace," by Gustave Brion; "A Jewish schoolboy of Tangiers," by Madame Henriette Browne; two charming groups of children, by Charles Chaplin; two pretty diminutive pictures, by Victor Chavet; two landscapes by Corot, in the great room, which were thought so admirable by half of the jury that they desired to bestow the grand prize upon that artist, and it was only finally awarded to Cabanel after 28 turns of the ballot-box—both being members of the jury; a fine moonlight scene, and a view of the park of Saint Cloud, by C. F. Daubigny; "Venus and Cupid," by Eugène Fauré; "View of the new excavations at Pompeii," by François; "Falconry in Algeria," and "Robbers of the Sahara," by Fromentin; "Portrait of a lad in Turkish costume," by Gautier; a "Presentation," and "Monks at their studies," by Gide; "The death of the Princess de Lamballe in 1792," by Firmin Gotard; "Arrival of the Emperor Napoleon III. at

Genoa," a marine scene, by Gudini; Two charming little works by Herbert, entitled "La Perle Noire" and "The Stone Seat;" "A child's head," by Leopold Horowitz; "The Alchemist," by Isabey; "A Scene on the Sea Shore," by Le Comte; "Hylas," by Lenepken; "Skarga preaching before Sigismund III.," an excellent attempt at historical painting by a young Pole, pupil of the school of Cracow, and for which a medal has been awarded to the artist, Jean Matejko; two works by Meissonier; and the first exhibited production of his son, Jean Charles; the last-named is on a larger scale than the works of the elder artist, but the treatment is of the same kind and promises well; "Jason," and a composition entitled "The Young Man and Death," by Gustave Moreau, the painter of the "Sphinx," which was the most remarkable picture of last year's *salon*; Interiors of the galleries of the Louvre and of Fontainebleau, by Navlet; "A fête in the time of Henry II.," by Arnold, son of Ary Schaeffer; "Cinderella," by a Belgian artist, Joseph Van Lérins; "The Empress Josephine before the coronation," by Viger-Duvignau; and two views in Venice and Verona by Mr. William Wyld. A large number of eminent names are absent from the catalogue, and some of the ablest of the exhibitors have sent works of small importance; but on the whole, however, there is such immense profusion and variety, such a general acquaintance with form, and so much power in its delineation, so much knowledge of colour and harmony, although, according to English notions in general, pitched in too low a key, that no young artist, who can afford to pay an annual visit to the Paris exhibition, should omit to do so. He can find nowhere else such a mass of contemporary art, or see at once the works of so many existing schools, for the Paris exhibition includes a large number of works by other than French artists. The total number of painters exhibiting is 1,567, of whom 1,800 are French, and 267 belonging to other countries. Of the latter 60 are Belgian, 34 Prussian, 31 from other parts of Germany, 21 Swiss, 19 Italian, 17 Russian, 17 Dutch, 14 Austrian, 12 Spanish, 9 English, 9 American, 5 Polish, and as many Swedish, 4 Norwegian, 3 Hungarian, 2 Danish, and as many Hanoverian, and one each from Portugal, Peru, and Egypt. But of these 267, rather more than one quarter, have been educated, either wholly or in part, in France, and thus belong to the French school. Of the wholly foreign element the Belgian is by far the most important, there being fifty artists educated in Belgian schools in the list of exhibitors. The next most important element is the Prussian, and indeed, taking the whole of Germany together, its artists rather exceed those of Belgium. Half the Swiss exhibitors have been educated in France, but less than a third of the Italians and Russians, while nearly the whole of the Austrians and Dutch are educated in their own countries. It appears by the official report itself that there were alive on the 1st of January in the present year 800 painters, 200 sculptors, 160 architects, and about 130 engravers and lithographers, who had received medals or other honours.

Manufactures.

ANGLO-FRENCH WORKING-CLASS EXHIBITION.—An International Working-Class Exhibition is now being organized by a committee of English workmen, with whom their French brethren appear to be heartily co-operating, and the present year being the fiftieth anniversary of peace between Great Britain and France, may be regarded as a peculiarly suitable opportunity for such an undertaking. It will be held at the Crystal Palace, Sydenham, and is to be opened on Saturday, July 29th, and to remain open during the months of August, September, and October. Among the patrons are M. Michel Chevalier, M. Girardin, M. Arles Dufour, Thomas Baring, Esq., M.P., G. J. Goschen, Esq., M.P., Stephen Cave, Esq., M.P., Charles Buxton, Esq., M.P., Walter Morrison,

Esq., M.P., Robert Hanbury, Esq., M.P., George Lyall, Esq., M.P., and J. G. Hubbard, Esq., M.P. English and French employers and workmen are invited to send specimens of skilled work; journeymen to exhibit in their own names; and employers, in addition to their own, must state the names of the men who made the articles shown. Clever workmen will thus have an opportunity of obtaining public recognition of their skill, while firms who employ them will, in all probability, extend their business by sending highly-finished goods to this the first international working class show. Prizes will be given for excellence of workmanship, and a bronze commemorative medal will be presented to every exhibitor as a souvenir of the peace jubilee. To enable exhibitors to superintend and arrange their goods, a free pass for the season will be issued to each person whose work is accepted; but the committee wish it to be distinctly understood that they do not bind themselves to accept every article offered. All articles sent for exhibition will be taken the greatest possible care of, but the committee will not hold itself liable for any loss or damage whatever. Things may be sold, but not removed until the close of the Exhibition. French workmen living in London are especially invited to compete with their British friends upon this occasion. It appears that a deputation from the London Committee was received with great enthusiasm in Paris; and at a meeting of delegates from the various Trade and Co-operative Associations held at the offices of the Society of Crédit au Travail a committee was formed who will receive goods from all parts of France and forward them to the Crystal Palace. From the ready support given to the movement by all classes in Paris, a very imposing collection of French goods is anticipated. English exhibitors are requested to make early application for space, which will be granted free, but all goods intended for exhibition must be delivered, carriage paid, at the Crystal Palace, not later than July 22nd. All articles not sold must be removed from the Crystal Palace within a fortnight after the close of the Exhibition at the exhibitor's own expense. For further particulars, forms of application for space, &c., apply to the Secretary, Mr. R. Coningsby, Crystal Palace, Sydenham; or to M. Edmond Potonie, 8, Rue Baillet, Paris.

MANUFACTURES IN IRELAND.—A meeting was held on the 12th instant, at 29, Cannon-street, to consider the best means for introducing new and extending existing manufactures in Ireland. The chair was taken by the Marquis of Clanricarde, and among those present were:—Lord Dunkellin, M.P.; Colonel Dunne, M.P.; J. Pope Hennessy, M.P.; J. F. Maguire, M.P.; J. A. Roebuck, M.P.; Colonel French, M.P., and many others. The Chairman said they had met to consider what description of manufacture should be introduced into Ireland so as to receive the support of English commercial men. He was sure if a company were formed it would receive the best support which himself and other gentlemen could give. Mr. J. O. Lever, M.P., then explained that the object proposed was to erect a number of mills in different parts of the country, for weaving union cloth, an article of extensive demand, composed of linen and cotton. They contemplated the erection of ten mills for the purpose, and proposed to employ a capital of £1,000,000, consisting of 5,000 debenture bonds, bearing 6 per cent. interest: £200,000, in 10,000 shares to be applied in payment for land, &c., in Ireland; a like sum to be applied in payment for machinery in Lancashire; and 5,000 £20 shares for allotment and distribution to the public. He had found some of the best engineers in England who were willing to supply the machinery, taking one-fifth of the cost in shares and giving reasonable time for the payment of the remainder. They contemplated employing a new patent of Mr. Dickson for spinning the cotton and flax in the same yarn, by which one of the objections to ordinary union cloth would be obviated. The cost of erecting the mills would be £1 per spindle. Mr. Maguire, M.P., did not think mills could be erected at so low a cost. Mr.

Kirk stated that the erection of mills at the price named was easily accomplished. Mr. Dickson said he had tried his plan to some extent, and it had proved remunerative. After some further discussion, the following gentlemen were appointed a committee to consider the subject:—The Marquis of Clanricarde; J. Ennis, Esq., M.P.; Lord Claude Hamilton, M.P.; J. F. Maguire, Esq., M.P.; Colonel Ffrench, M.P.; R. P. Dawson, Esq., M.P.; J. O. Lever, Esq., M.P.; and J. Pope Hennessy, Esq., M.P.; with power to add to their number.

Colonies.

THE CENSUS OF CANTERBURY gives the population of the province at 32,253 souls, of whom 18,932 were males and 13,321 females. The total number of acres of land fenced was 842,416, of which there were in wheat, 18,328 acres; in oats, 14,672 acres; in barley, 2,432 acres; in maize, 107 acres; in potatoes, 1,752 acres; in gardens and orchards, 220 acres; in artificial grasses, 81,670 acres; and other crops, 2,564 acres. The stock returns of the province give 10,868 horses, 62 mules and asses, 45,263 cattle, 1,567,320 sheep, 769 goats, 10,228 pigs, and 73,745 poultry. The census of 1862 gave the population at 16,940, so that it has more than doubled in three years.

THE STATISTICS OF WELLINGTON show the population of the province to be 14,988, an increase during the last three years of about 18 per cent. The total quantity of land under crop, exclusive of artificial grasses, was 8,130 acres. Of land under grass there were 90,286 acres. The live stock—7,265 horses, 49,200 cattle, 401,502 sheep, pigs 13,072.

TRADE OF MARYBOROUGH, QUEENSLAND.—The gross value of the imports during 1864 was £112,412, and the gross exports during the same period were £123,246, and it is expected this year that coal, sugar, and other articles will be seen in the list of exports.

PROGRESS OF QUEENSLAND.—Marked progress was made last year in the Wide Bay district. Notwithstanding the severe test brought to bear on the farming population by the disastrous floods at the commencement of the year, the agricultural prospects are very promising. A large quantity of land has been taken up during the year, and a considerable increase made to the number of farmers resident on the Mary. Much attention has been directed to sugar-growing. A large area has been devoted to the growth of the cane, and two sugar mills are being obtained from England. During most of the year the timber trade has been greatly developed, and the immense cedar and pine forests have been keeping three local saw mills in active employment. Pastoral interests have been steadily advancing. The Burnett, although tested by two or three wet seasons, has maintained its high reputation for the growth of wool and healthiness of its sheep; and while other parts of the colony have been suffering from pleuro-pneumonia, neither the Wide Bay nor Burnett has exhibited a solitary case of that deadly scourge. A very fine seam of coal has been discovered on the Upper Mary, cropping out on the bank of a navigable portion of the river.

Notes.

GEOLOGISTS' ASSOCIATION.—The first excursion of the season took place on Tuesday, the 9th inst., when the members visited Swindon, to examine the beautiful sections of Portland oolite, Purbeck, and green sand, which are displayed in the quarries of that neighbourhood.

WORKING MEN'S EXHIBITION FOR THE CITY OF LONDON.—A deputation of members of the committee formed for organising a "Working Men's Exhibition for the City of London," waited by appointment upon the Lord Mayor on Thursday, the 11th May, to present a requisition signed by nearly 2,000 working men, and to solicit his

lordship's co-operation in promoting such an exhibition. The deputation was introduced by Mr. Deputy Obbard. His lordship consented to take the matter into consideration and communicate with the secretary at an early date.

Correspondence.

WEAR AND TEAR OF STEAM BOILERS.

SIR,—A letter from Mr. D. K. Clark, in your last impression, conveys against me a charge of plagiarism in a way as courteous as it appears to me unmistakable. If I do understand that gentleman rightly, he labours under the slight misapprehension of thinking that I derived the explanations I gave of the pitting and furrowing of boiler plates from his work on the "Recent Practice in the Locomotive Engine." As he was so good as to re-publish last week, in your columns and those of a contemporary, all he has written on these subjects, and as I had the pleasure of laying the results of my little investigations before the Society on the 26th ult., anybody who chooses to take the trouble can easily form his own opinion on the sufficiently-unimportant question at issue. But I fear that few will take this trouble, and therefore, in justice to myself, I shall now proceed to show, in an easily-accessible form—

1. That my explanations, such as they are, of the phenomena of pitting and furrowing are quite distinct from those given by Mr. D. K. Clark.

2. That everything which he adduces as explanatory of furrowing and pitting was published by others years before the issue of his work on the "Recent Practice in the Locomotive Engine."

3. That such publication could hardly have been unknown to Mr. D. K. Clark at the time (1860) he published his own book.

4. That the very little information I have derived from his work has been fully acknowledged by myself.

I will now proceed to prove these small matters by a verbatim reference to the original documents:—

MR. D. K. CLARK'S THEORY,
in extenso, OF THE PITTING
OF BOILER PLATES.

(Published in 1860, at page
15 of "Recent Practice in
the Locomotive Engine.")

"Furrowing of Boilers at the Joints.—Probably the most important practical reference to be drawn from the tests of the strength of rivetted joints, is the explanation they supply of the failure, hitherto unexplained, of boiler plates, not at the joints, but in their neighbourhood. We are aware that electrical and galvanic action are freely adduced in explanation. But these words have two meanings—they mean electricity and galvanism; and they mean ignorance and mystery. It is known that boilers fail by corrosive and other agencies eating into the plates on the inside, pitting and furrowing the surface. The pitting of the metal is readily explained by the presence of chemical agents in solution in the water, and the known inequality of substance of iron plates and bars, in consequence of which the metal is gradually but unequally separated and dissolved; and probably a weak

APORTION OF YOUR CORRESPONDENT'S EXPLANATIONS.

(See the "Society of Arts' Journal" of April 28th, p. 394.)

"..... The presence of a concentrated solution of an acid or alkaline character, kept at a high temperature for years in contact with iron plates, would be sufficient to account for much corrosion. But the internal corrosion of steam boilers has many features of such a mysterious character, that no accredited explanation of its attendant phenomena has yet been put forward. In the first place, plates thus attacked show a number of irregular holes, like a pock-marked human face, or like the small craters seen on the moon's surface. The writer has also sometimes observed two or three little irregular excavations like this in a plate otherwise showing a large surface quite intact. Sometimes the plate is most pitted round a projecting bolt; at others, one plate will be perfectly sound, while that rivetted to it will be almost eaten away, both having been the same time at work, and under, of course,

galvanic circuit may be established between the iron shell and the brass tubes, accelerating the process of dissolution."

Most of the above is contained, almost verbatim, in the following letter, addressed by Professor Tyndall to Lieut.-Col. Wynne, R.E. It was printed and published in 1856, in the very same "Report of the Board of Trade on Railway Accidents" to which Mr. D. K. Clark refers at page 15 of his book. This letter was also included in a circular sent, in 1855, to all the railways in the United Kingdom by the Board of Trade.

"MY DEAR SIR,—In placing before you the reflections suggested by our joint examination of the boiler which exploded some time ago at the Swindon Station of the Great Western Railway, I have to express my regret that the absence of safe experimental data on the question of steam boiler explosions generally renders every opinion upon the subject in a great degree conjectural and uncertain. Our two hours' examination, instead of enabling us to assign the exact source of the actions which led to the destruction of the boiler, merely suggests the mode of attacking the question. While venturing, therefore, upon the following remarks, I cannot help feeling how much more satisfactory it would be to be able to substitute for supposition, however probable, the surer evidence of experimental fact.

"The appearances presented by the boiler were as follows:—The iron plates, as far as the water usually extended, were deeply pitted and furrowed by some corrosive agency. At the centre portion of the boiler, the pits, I think, were deepest and best defined; towards the end at which the cold water entered to feed the boiler they were less pronounced; towards the end nearest to the fire-box they were more diffuse and general. While pondering over these curious appearances, my attention was attracted by the tubes which passed through the boiler; these were of brass, and were attached at one end to the fire-box, and at the other end to the smoke-box of the engine. In the normal condition of the boiler these tubes were separated from the bottom and sides by an interval of an inch or two, this interval being usually filled with hot water.

"Without pretending to a degree of confidence unwarranted by the circumstances of the case, I think it may be

apparently exactly similar conditions. With locomotive boilers this pitting has been ascribed to galvanic action between the brass tubes and the iron plates. But it is notoriously well-known to locomotive superintendents that boilers with iron tubes are often worse pitted than those which have run the same distance with brass tubes. Besides, all iron boilers, with or without brass, whether used for stationary, locomotive, or marine purposes, are subject to pitting.

"An explanation which seems to meet all the circumstances of the case is the following:—Mr. Mallet, in a report addressed to the British Association some years ago, showed that wrought iron and steel (blister steel probably) 'consist of two or more different chemical compounds, coherent and interlaced, of which one is electro-negative to the other.' In fact, ordinary wrought iron, being also welded up from differently worked scrap, is far from being an electro-homogeneous body. In a boiler, the hot water, more or less saturated with chemical compounds, is the exciting liquid, and the electro-positive portions of the plates are thus quickly removed to a greater or less depth. This explanation meets most of the known circumstances with respect to pitting; it even, in a great measure, explains how plates above the level of the water, especially in marine boilers, get very rapidly corroded in portions, while another part of perhaps the same plate is scarcely affected. The concentrated water in a marine boiler is known to be generally acid. 'Of all the salts contained in sea water,' says Faraday, 'the chloride of magnesium is that which acts most powerfully on the plates. He shows that a cubic foot of sea water contains 3·28 oz. of this salt, and at the same time, points to the danger of voltaic action in a boiler through the contact of copper and iron. In a smaller degree, the contact of cast with wrought iron, or between the different makes of wrought iron in the same plate, or between contiguous plates, acts in the same way. It is not improbable that some hydrochloric acid is present in the steam of marine boilers.' Mr. J. C. Forster has tested some of the condensed steam from the safety valve casing, and from the cylinder jacket of the Lancashire, and found both decidedly acid. With an exciting liquid in the condensed steam, it is thus explicable how the plates of marine boilers often get corroded in a most capricious

affirmed that such a boiler constitutes a veritable voltaic couple, consisting of brass, iron, and the exciting liquid, water. Feeble currents of electricity will be established, the direction of which through the liquid will be from iron to brass, the iron being what is called the positive element of the couple. A decomposition of the water will take place, hydrogen will be liberated against the brass tubes; oxygen (and acid, if a salt be dissolved in the water) will be liberated against the iron plates. The quantity thus evolved may be very small, but, acting incessantly for a number of years, it would, I imagine, be sufficient to produce the observed corrosion.

"In the course of our examination you directed my attention to the singular preservative influence which the fire box seemed to exercise on some iron bars which passed through it. There were, I believe, four such bars—solid cylinders, which passed, as longitudinal stays, from the front to the rear of the engine. Up to the point where these bars entered the steam dome they were deeply corroded; in the steam dome they were comparatively unaltered. This seems to be in harmony with the foregoing explanation. Up to the steam dome the iron bars ran side by side with the brass tubes which traversed the boiler; at the steam dome the brass tubes ceased, and from this to the end of the boiler, the iron bars, instead of being electromotors, were merely the conductors of the currents generated where the bars and the tubes were in close proximity. Other explanations may possibly be suggested, the exact merits of which experiment alone can decide.

"Parallel to the row of rivets which united the bottom plate of the boiler to the smoke-box, a deep furrow had been eaten into the plate. A similar corrosive action was not observed parallel

to the corresponding row of rivets at the fire-box end. Parallel to one longitudinal row of rivets a furrow had been eaten as deep as to reduce the thickness of the plate from three-eighths to less than one-eighth of an inch. Along this furrow the boiler is supposed to have given way; the plates were torn asunder, and the total destruction of the boiler was the immediate consequence.

"Now, whatever be the cause of the corrosion, whether we refer it to the oxygen held in solution by the water, or to the decomposition of the water itself, science probably furnishes the means for its prevention. The experiments of Poggendorff, Davy, Van Beek, and others show that, by suitably connecting a more positive metal with iron, the corrosion is diverted from the latter, so that it is thus possible to preserve iron unharmed in a liquid which, under ordinary circumstances, would rapidly attack it.

"If the explanation which refers the corrosion to electro-chemical decomposition be the correct one, then in boilers where iron tubes are used, instead of brass ones, the pitting and oxidation ought not to take place to the same extent. I say 'to the same extent' because a difference in the manipulation of two pieces of iron is sufficient to destroy their electro-homogeneity, and to produce feeble currents when the pieces

manner; while, at the same time, the current of steam would create a certain amount of friction on the oxide, clearing it away to act on a fresh surface.

The crucial test of this explanation of pitting would be the observation of the absence of the phenomenon from plates of an electro-homogeneous character. This homogeneity could only be expected from fused metal, such as cast steel. Accordingly, while the writer was in Vienna a short time ago, he was assured by Mr. Haswell, the manager of the Staatsbahn Locomotive Works, that some locomotives made of cast steel plates, in 1854, for the Austrian Staatsbahn, had been working ever since without showing signs of pitting, though under similar conditions iron plates had severely suffered in this way. Pitting may thus be fairly defined as a form of corrosion localised to particular spots by voltaic action. It is also probably aggravated through the motion of the plate by mechanical action, and the expansions and contractions from alterations of temperature. All boilers are most pitted near the inlet for the feed water, and with inside locomotive boilers there is generally more pitting at the smoke-box end—no doubt caused by the more or less racking action on these plates. A state of corrosion at particular spots would probably be kept up to a greater intensity by the incrustation being mechanically thrown off. With a quicker voltaic action caused by any unusual intensity of the exciting liquid, the sides of the cavities in the plates would be sharper, and less rounded off; as in the case of the boiler fed with mineral water from ironstone workings, which exploded last year, at Llan-aman, South Wales."

are immersed in an exciting liquid. An action of this kind may, perhaps, be established between the iron rivets and the plates they unite, and, possibly, to this cause may be referred the furrows which are sometimes observed to follow the lines of junction. It would, however, be hasty to infer from a single instance that this is a general result; the whole subject demands a thorough examination, and a far wider acquaintance with facts than two hours' inspection of a single boiler could possibly furnish.

"The longer we reflect upon this subject, the more deeply must we be impressed with the necessity of associating, in the construction and management of steam boilers, the knowledge of the natural philosopher with that of the engineer. The consciousness of our deficiency in this respect was present with me when, on a recent occasion, I ventured to state that 'there are agencies at work in a locomotive of which the maker of it never dreamed, and which may, nevertheless, convert it into an engine of destruction.' At the present moment it might be difficult to say how many boilers are on the verge of explosion without any single engineer being aware of the danger. Another point deserving of attention is the following:—Common water always contains a quantity of atmospheric air in solution. This air may be expelled from the liquid by continued boiling, and it is an experimental fact that water thus freed from air possesses mechanical properties widely different from ordinary water. The cohesion of the liquid is enormously increased, in consequence of which it may be heated to a temperature far beyond its ordinary boiling point without boiling; but when it does boil it is not with the quiet ebullition of common water, the liquid particles snap suddenly asunder like a broken spring, and ebullition is converted into explosion. It is, I believe, a fact that boilers, after standing for a time, have often exploded at the precise moment when the engineer turned on the steam. The question presents itself, whether the action just referred to may not here come into play? If the water has been sufficiently purged of air and then left at rest, its augmented cohesion may permit of its being heated far above the boiling point due to the pressure upon its surface; the mechanical disturbances produced by turning on the steam would destroy this cohesion, and the superheated liquid would develop a force resembling that of gunpowder on the application of a lighted match. I would wish it to be borne in mind that we are in total ignorance as to the practical value of these suggestions; but the investigation which the subject so pressingly demands must take cognizance of them all.—I am, &c.,

(Signed)

JOHN TYNDALL.

"Lieut.-Col. Wynne, R.E., &c., &c."

The explanation I put forward differs, therefore, *in toto* from that of Mr. D. K. Clark. He first accepts the common stoker's notion of pitting, and ascribes it to some parts being "softer" than others. With this he jumbles up Professor Tyndall's observation about the brass tubes. He is entirely unaware of the three facts, amongst others, the bringing together of which has enabled me to put forward an explanation of the pitting of steam boilers:—1. That boilers with iron tubes are often more affected than those with brass tubes; 2. That cast steel boilers are not affected in the form of pock marks at all; 3. That common plate consists of interlaced portions, which are not electro-homogeneous—an important observation first made by Mr. Mallet, whom I quote. The weak galvanic circuit between the iron shell and the brass tubes, first alluded to by Professor Tyndall, and then adopted by his disciple, Mr. Clark, might account for an equally spread corrosion, but not for the "pock-marks." In truth, it has been noticed by many observers, amongst whom is Professor Faraday, that ordinary zinc plates in a galvanic battery are pitted in just the same way, and with an attendant loss of discharging force. Of course, Mr. D. K. Clark may have known every one of these things, but it was scarcely kind to his readers not to have published them.

MR. D. K. CLARK'S THEORY, A PORTION OF YOUR CORRESPONDENT'S EXPLANATION
in extenso, OF FURROWING.
 " . . . But this explanation does not meet the frequent case of a straight continuous furrow, cut like a groove, upon the surface. Furrows are observed to be formed parallel

to, and close to, the rivetted joints. Not in any case, that we are aware of, have they been found at any notable distance from a rivetted joint, nor otherwise than parallel to one. The inference is inevitable that there is a relationship betwixt them; and our conviction is, that the alternate tension and relaxation of the plates at the joints, as the steam is got up and let down, are attended by an alternate distortion—incipient it may be—and resumption of the normal form, a bending and unbending of the plate on each side of the joint; in consequence of which the texture of the metal is gradually loosened in lines near to, and parallel to, the joint, and it is thus open to corrosive action. On this interpretation, the commencement of a groove or furrow, establishing a weak place, and concentrating the action there, would suffice to extend and deepen it to the dangerous limits occasionally announced by explosion.

"The weakness attendant on lap joints is strikingly exemplified in the lap-welded joint when subjected to extreme tension; the tensile strength, though the metal at the weld is perfectly solid and fully as strong in itself as the body of the plate, is much below that due to the regular section of the plate. Here there is no elementary weakness in the reduction of metal by rivet-holes; the inferiority of strength arises solely from the bending of the plates on both sides of the lap, and the overstraining of the fire-box in the endeavour to attain the position of stability.

"Mr. John Sewell, commenting on the corrosion of locomotive boilers, ascribes the furrowing of plates at rivet joints to the interruption of the vibrations of the boiler by these joints, the localisation of the fatigue at these places, and the increased susceptibility, in consequence, to corrosive action. This action has, doubtless, a tendency to aggravate the evil of lap-jointing; but we are disposed to ascribe the evil to the lateral bending and unbending of the plates as the primary cause.

"The furrowing of lap-jointed plates reads an important lesson on the real and intimately practical value of direct connection and direct action in exerting, transmitting, or resisting forces. That the furrowing of plates at the rivetted joints results from the indirectness of the strain of the steam pressure, is rendered still more probable by the analogous furrowing which results from reciprocating strains of another kind. In the more ancient classes of engines, in

the pressure of a fluid from the interior, is as the diameter of the pipe and the fluid pressure. He also showed 'that the stress arising from any pressure, upon any part, to split it longitudinally, traversely, or in any direction, is equal to the pressure upon a plane drawn perpendicular to the line of direction.' As in a boiler the thickness of the metal is small compared with the radius, the circumferential tension has been assumed to be uniformly distributed; and the strain per unit of length upon the transverse circular joint being only half that upon the longitudinal joints, the strength of the latter has been taken as the basis of the calculations for the tensile strength of the joints. But in taking the internal diameter of the boiler as the point of departure, the internal section has been assumed to be a correct circle, which would only be practically true in the case of a cylinder bored out in a lathe, and never in that of a boiler. Two of Emerson's corollaries from his first proposition have in fact been neglected. He shows that if one of the diameters be greater than another, there will be a greater pressure in a direction at right angles to the larger diameter; the greatest pressure tending to drive out the narrower sides till a mathematically true circle is formed. The second is that if an elastic compressed fluid be enclosed in a vessel, flexible, and capable of being distended every way, it will form itself into a sphere.* A number of proofs can be adduced that both these influences are more or less at the bottom of the wear and tear caused by the direct action of the steam.

"From 1850 to 1864 forty locomotive explosions, causing a loss of human life, have occurred in the United Kingdom. The Board of Trade reports in the blue-books presented to Parliament, and more especially those by Captain Tyler, R.E., probably form the most valuable and connected series

* The action of a fluid pressing with equal forces in all directions can be evidently represented as to force and direction by innumerable radii of equal length led from a single point in all directions. Upon this principle may be explained the spherical shape of soap bubbles, or the bulbs of thermometers (blown while the glass was in a plastic state), of the thin india-rubber balls used as playthings, and which are formed by forcing air into india-rubber tubes closed at one end. Gas and air bubbles in water are necessarily flattened by the hydrostatic pressure. It is upon that principle that a gun of soft ductile iron often bulges out at the breech.

which the cylinders are fixed to, and work from, the smoke-box plates, the alternate forward and backward strains by the steam pressure on the piston have been observed to weaken, and to subject to corrosion and leakage, the substance of the plate along the edge of the angle-iron at the junction with the barrel. In further corroboration of this doctrine, Mr. Colburn states that he is not aware that any accidents from furrowing of boiler plates have taken place in the United States; and we believe that their immunity from accidents from this source is to be ascribed to the use of very thin boiler plates, quarter to five-sixteenths of an inch thick." (Pages 16 and 16.)

We will now see whence Mr. D. K. Clark got his notion "that the furrowing of plates at the rivetted joints results from the indirectness of the strain of the steam pressure." At page 6 of his work I find that he mentions, *en passant*, an able pamphlet published by Mr. A. H. Renton, O.E., in 1856, on Bertram's patent welding process (London: J. Scadding). This gentleman also furnished Mr. Clark with a number of experiments made at Woolwich by the Admiralty, in order to test the resistance of plate joints, and more especially Bertram's joint.

"The comparative strain," says Mr. Renton, "which the samples of single rivetting bore (though in some slight degree influenced by its length) was from 40 to 60 per cent. of that borne by the solid plate, the thinner plates bearing the larger proportion—that is, the strength of the three-eighth inch lapped plates was 60 per cent. of that of the solid plates, while that of the half-inch plates was only 40 per cent., whereas the proportionate section of metal between the rivets was $62\frac{1}{2}$ per cent. in both cases.

"It will be obvious from a reference to Tredgold's formula in the first vol., 'Trans. Inst. Civ. Eng.,' that the resistance of any given section, when the line of the straining force is not in the axis of the material,

is in the ratio of

$$4t - 6d$$

compared with that of the coincidence of the two as unity, in which d is the distance between the nearest side of the section and the axis or line of the force applied, and t , the thickness of the plate, from which it is evident that the resistance decreases in a much

of records extant on boiler explosions. This is more especially the case with regard to wear and tear caused by the direct action of steam unmasked by the effects of the fire, as the barrel and outside fire-box of a locomotive cannot be said to be under the direct action of the heat. Perhaps the vibration of the boiler through the motion on the line may intensify this action, but it is clear that vibration cannot be a primary cause. The majority of the reports are illustrated by careful drawings. Eighteen of the forty boilers gave way at the fire-box—eleven from the crown of the inside fire-box being blown down upon the tube plates; seven from the shells or sides giving way; twenty burst at the barrel; and two may be ascribed to miscellaneous causes, from an originally defective plate, and from running off the line. Leaving out all those which occurred at the fire-box, as the majority of these might be ascribed to other influences than direct pressure, all the twenty explosions of the barrel could be traced either to internal furrows or to cracks, both running parallel with one of the longitudinal joints of one of the rings forming the barrel. All the joints which thus gave way were lap-joints; and the furrows or the cracks (and the former greatly preponderate in number) occur at the edge of the inside over-lap, and therefore, just at the point where the diminution of diameter caused by the lap-joint would be most affected by the pressure of the steam.

"The plate at the channels shows distinct traces of lamination through the cross-bending, and it is probable that plate of a good material will gradually laminate, while inferior metal will crack through in less time. Nor are these furrows found with only lap-joints. Butt-joints, with a strip inside the boiler, and thus destroying the equilibrium of internal pressure, have been found to be attended with similar furrows. Channels of exactly the same character have been observed in locomotive boilers with lap joints, which have exploded in Germany.*

"Similar furrows, again, have been noticed in marine boilers, and in old boilers generally, longitudinal furrows being, of course, about twice as dangerous as those appearing transversely. The smoke-box tube plates of inside cylinder locomotive engines have been

higher ratio than the area of the section increases; and hence the inadequacy of an increased thickness of plate to obtain a proportionate increase of strength—an objection to which the scarf-welded joint is not liable, as the full strength of the plate is always obtained."

As to Mr. D. K. Clark's having first put forward the explanation that furrows are caused by an alternate buckling of the plate, such an illusion would be dispelled by a perusal of the late Mr. Frederick Braithwaite's paper, "On the Fatigue of Metals," read in 1864, before the Institution of Civil Engineers. This brief explanation, due to Mr. Braithwaite, was adopted by Mr. D. Gooch, in a letter to the Board of Trade, published four years before the issue of Mr. D. K. Clark's book. Similarly, in 1859, Mr. Adamson, of Hyde, discussed these matters of furrowing before the Institution of Mechanical Engineers of Birmingham, as an action well known by engineers to be due to alternate buckling, or, indeed, to anyone who had bent to and fro a piece of wire or of plate.

This action is progressive, and probably very rapid towards its later stage. Once a weak place formed itself, it would have to do more and more of the work. Even when pulled by the direct tension of the testing machine, a lap-joint behaves in a somewhat similar way. For instance, a $\frac{1}{2}$ -in. lap, solidly welded by Bertram's process, has only half the strength of the solid plate; while the three-eighths of an inch lap-weld has actually two-thirds of the strength of the solid plate....

"There is, however, another important appearance to be noted with respect to these furrows. An iron cylindrical vessel under internal pressure would, of course, rupture long before it could assume a spherical shape, from its ranges of elasticity and of ductility being so short. But it may be said to be undergoing three distinct stresses in as many directions. There is a stress acting on the ends, and tending to rupture the boiler in two halves in a direction parallel to the axis; there is the stress which is hoop tension in a true circle, but which acts with a cross bending strain in an ordinary boiler; and there is the stress which tends to make it assume the shape of a barrel, or to bulge it out in the centre of its length. The precise action on a material of several strains like this is a portion of the strength of materials which is still completely unknown. Its probable effects might be illustrated by the case with which a stretched india rubber ring is cut through with a knife, or that with which a column under compression is broken by a blow from a hammer, or by the similar case with which a tube under tension is split by a sharp blow; in fact, the operation of caulking a defective boiler under steam seems to often give it the finishing stroke which causes an explosion. The new boiler which burst from a defective plate at the Atlas Works, Manchester, in 1858, and that which burst through a crack at a longitudinal joint last January at Peterborough, both gave way whilst being caulked. This again accounts for the fact that adjacent boilers sometimes explode one after the other, pointing, at the same time, to the danger into which a sound boiler may be thrown by an explosion. Upon the same principle it is probable that the modern guns, built up from strained rings, will be easily put hors de combat by shot. The probability is that a number of

found to be similarly influenced by the racking action of the engines, showing furrows around the cylinder flanges. A parallel case is often found in Lancashire with the end-plates of double-fired Fairbairn boilers, which may have been too stiffly stayed to the barrel. Circular furrows, caused by the confined motion of the end-plates are sometimes found at the base of the angle iron rings jointing the internal flues to the end-plates. But furrowing seems with no kind of boiler to be more felt than with locomotive boilers. This is due to the high pressure, the thicker plates causing a coarser lap, and more especially to the fact that the unstayed barrel cannot be thoroughly examined without drawing the tubes, thereby enabling the furrow to enlarge itself unnoticed.

"The inside fibres of a plate bent up while cold are necessarily initially in a state of compression. When the pressure from the inside comes on, striving to form a perfect cylinder, the plate gets bent to and fro by its own elasticity on one side, and by the pressure on the other. If the iron be brittle, it may crack right through; if ductile, the outside fibres gradually lose their elasticity, and, necessarily aided by other causes, crack away.

* Organ für die Fortschritte des Eisenbahnwesens. 1:61, p. 159.

simultaneous strains in different directions diminish the elasticity of the material that would allow it to yield in any given direction. However this may be, it will be seen that it is only the pressure on the ends of the boiler acting parallel to the axis, and tending to tear the cylinder through transversely, which bears fairly on the rivetted joint, or rather on that metal between the rivets which is left after punching. Unless the cylinder be perfectly correct inside, the circumferential strain resolves itself into cross bending, shifting the dangerous section from the iron left after punching to the metal at the over-lap. With respect to the stress tending to bulge the cylinder in the centre, it is clear that if we suppose a strip cut out from the entire length of the boiler, each portion of the length of this strip could be regarded as a beam under an uniformly distributed load. As, however, with the lap joint there is a double thickness of metal transversely, that joint is the strongest and stiffest portion to resist the stresses tending to bulge out the cylinder in the middle, and also to tear it into two halves. This affords some justification for the belief of old boiler-makers before rivetted joints were tried under a direct tensional load, that the joints are the strongest parts of the boiler. And, indeed, this is what we find in practice. The thinnest portion of the longitudinal furrows is generally exactly in the middle of the plate, and this is caused by the longitudinal stress, which is acting at right angles to the transverse cross-bending stress. A strip cut from joint to joint is, in one respect, in the condition of a beam supported at both ends, uniformly loaded throughout its length, and, according to known principles, therefore giving way in the middle."

Now, if there be any virtue in words, it is clear that Mr. D. K. Clark simply assimilates the strain on a lap-joint, when made up into a boiler shell, to the tension which it undergoes by means of the straight pull of a testing machine. Amongst other little things forgotten by him is, therefore, the tendency of the imperfectly circular shell to form a correct circle. This does not, correctly speaking, cause what Mr. Clark terms "indirectness of strain," but complete cross-bending. Perhaps Mr. Clark will favour us with an explanation of the fact that butt-joints, with a covering strip inside, and with which, in the testing machine, there can be no "indirectness of strain," also lead to furrowing, while, when the plate is *outside*, no furrowing is found to take place. Mr. D. K. Clark next states, "In addition, my explanation of the destructive action of unequal expansion of the fire-box of locomotives and the shell, upon the stay bolts, in straining them laterally beyond the limits of elasticity, and thus permanently weakening them, was published at the same time [Recent Practice, pp. 16, 17], and, I think, anticipates *all* that Mr. Paget has just written on the same subject." Having been vainly striving to find an application of this assertion, perhaps Mr. D. K. Clark will kindly substantiate it by pointing to the passage in his work. I see, however, that, at page 10, the author proposes to strengthen fire-box stay bars "by straining them beyond the limits of elasticity," an operation which appears to "destroy" stay bolts, though it improves stay bars.

The only information I have borrowed from Mr. D. K. Clark's book on "Recent Practice in the Locomotive Engine" are the results he publishes of the tests conducted by the Admiralty on Bertram's welded joints. This I have acknowledged by a reference.

F. A. PAGET.

like many others of more recent western discovery, as old as the hills in the far East. Were some of those gentlemen to put themselves on board a steamer, and take a run round to Hong Kong, they would not only improve their health by a delightful two weeks' trip, but also have the pleasure of discovering for themselves the fact, that in that colony, as in China generally, tea oil is in common use for domestic purposes. In my own household, during my sojourn in that part of the world, I never used any other oil. Tea oil burns with a clear, bright light, and is free from unpleasant odour. This is one more illustration of the adage, that "There is nothing new under the sun." J. B. S.

MEETINGS FOR THE ENSUING WEEK.

- MON. ...R. Geographical, 1. Annual Address, "On the Progress of Geography." By Sir R. Murchison, K.C.B.
TUES. ...Medical and Chirurgical, 8.
Civil Engineers, 8. 1. Discussion upon Mr. Fletcher's Paper, "On the Maintenance of Railway Rolling Stock." 2. Sir Charles T. Bright, "The Telegraph to India, and its Extension to Australia and China."
Zoological, 8.
Ethnological, 4. Annual Meeting.
Royal Inst., 4. Prof. Frankland, "On Organic Chemistry."
WED. ...Society of Arts, 8. Mr. T. M. Gladstone, "On Anchors and Cables; their History, Varieties, and Properties."
Geological, 8. 1. Mr. Joseph Prestwich, F.R.S., "Additional Observations on the Raised Beach of Sangatte, with Reference to the Date of the English Channel, and the Presence of Loess in the Cliff Section." 2. Messrs. Clement le Neve Foster and William Topley, "On the Superficial Deposits of the Valley of the Medway, with remarks on the Denudation of the Weald."
Archaeological Assoc., 8.
Linnæan, 8. Annual Meeting.
THURS. ...Antiquaries, 8.
Royal Inst., 4. Prof. Frankland, F.R.S., "On Organic Chemistry."
FRI. ...Royal Inst., 8. Dr. H. Benze Jones, "On the Determination by the Spectrum Analysis of the Rate of Passage of Crystalline Substances into and out of the Tissues of the Living Body."
SAT. ...R. Botanic, 8.
Royal Inst., 4. Mr. Alexander Herschel, "On Meteorology."

PARLIAMENTARY PAPERS.

SESSIONAL PRINTED PAPERS.

Delivered on 29th April and 1st May, 1865.

- Par. Numb.
90. Bills—Merchant Shipping Disputes.
116. " Union of Benefices Act Amendment.
119. " Mortgage Debentures (amended by the Select Committee, and on re-commitment).
120. " Land Debentures (amended by the Select Committee, and on re-commitment).
121. " Land Debentures (Ireland) (amended by the Select Committee, and on re-commitment).
52. (III.) Trade and Navigation Accounts (31st March, 1865).
90. (IV.) Civil Service Estimates (Class IV.).
212. Public Debt—Account.
209. Illicit Distillation (Ireland)—Return.
211. Mails (India, China, and Australia)—Memorial.
217. Bradford (York) and Keighley Unions—Returns.
224. Judges' Lodgings—Return.
226. Rateable Property (Ireland)—Return.
Mr. Cobden—Despatch from M. Drouyn de Lhuys.
123. Bill—Constabulary Force (Ireland) Act Amendment.
203. Parsonage Houses—Returns.
207. Fisheries—Account.
216. Wexford Harbour—Returns.

SESSION 1864.

- 507 (A x). Poor Rates and Pauperism—Return (A).
123. Bill—Bank Notes Issue (as amended in Committee, and on Re-commitment).
66 (VII). Railway and Canal Bills—Eighth Report from the General Committee.
186. East India (Staff Corps)—Return.
195. Population, &c.—Return.
222. Greenwich Hospital—Paper.
233. Tenure and Improvement of Land (Ireland)—Return.
237. Barracks (Ireland)—Return.
67 (VII). Committee of Selection—Eighth Report.
90. Civil Service Estimates—General Abstract.
205. Poaching Prevention Act (Cases Reported)—Return.
205 (I). Poaching Prevention Act (Expenses of Prosecutions)—Return.
227. Royal Dockyards—Papers.

OIL FROM TEA SEED.—SIR,—In the *Journal* of the 21st April, I notice the following extract from the *Englishman*:—"It has lately been an important question among the tea planters what to do with the large quantity of tea-seed now available. It will, therefore, be an interesting fact for them to learn that a trial was recently made at Calcutta to produce oil from tea-seed. The result would seem to prove that three maunds of tea-seed will yield about one maund of oil. This oil is similar in appearance to olive oil." I cannot help feeling a little surprise that the *Englishman* and the tea planters of India should have to learn this "interesting fact" so late in the day—a fact,

239. Civil Service Estimates (1865-6)—Abstract showing Grants proposed, the sums voted "on account," and sums required to complete the several Grants.
248. Greenwich Park (South Eastern Railway—Minutes of Proceedings).
- Commercial Reports from Her Majesty's Consuls in Japan.
124. Bill—Bank Notes (Ireland).
181. Militia Regiments (Establishment)—Return.
228. Public Income and Expenditure—Account.
231. Azeem Jah (Signatures to Petitions)—Report, Evidence, &c.
245. Eschequer Bonds—Account.
- Commercial Reports from Her Majesty's Consuls in China.
113. Bills—Greenwich Hospital.
124. Bank Notes (Ireland) (corrected copy).
200. South Eastern of Bengal or Mutiah Railway Company, &c.—Returns.
213. East India (Employment of Officers)—Returns.
223. Inland Revenue (Scotland)—Statements.
228. Belfast College—Returns.
230. Courts of Probate (London and Dublin)—Accounts.
231. Azeem Jah (Signatures to Petitions)—Corrected pages.
236. Foreign Sugar—Account.
238. Emneth Parish—Correspondence.
241. Sheep (Ireland)—Return.
242. Queen's Colleges (Ireland)—Return.
244. Fortifications—Account.
246. Russian Epidemic—Letter.
249. National Portrait Gallery—Eighth Report.
252. Manchester Spring Assizes—Return.
254. Bradford (York) and Kelghley Unions—Letters.
3. (301 to 303) Railway and Canal, &c., Bills—Board of Trade Reports, Parts 301 to 303.
- Ordinance Survey and Topographical Depot—Report.
- Public General Acts—Cap. 1 to 16.
117. Bill—Salmon Fishery Act (1864) Amendment.
- 3 (304). Railway and Canal, &c., Bills—Board of Trade Report, Part 304.
228. Liabilities (Great Britain and Ireland)—Return.
232. Dale Dyke Reservoir—Reports of the Engineers.
240. Poor Law (Able-bodied Paupers)—Return.
263. Military Reserve Funds—Account.

Patents.

From Commissioners of Patents Journal, May 12th.

GRANTS OF PROVISIONAL PROTECTION.

- Animal charcoal, reburning of—1193—T. White.
- Artificial arms and hands—1186—W. E. Newton.
- Bearings for mechanical purposes—109—F. G. Mulholland and T. Dugard.
- Beds and bedsteads, folding—1228—W. E. Newton.
- Bottles, removing corks from the interior of—1132—G. Haseltine.
- Bread, &c., baking of—1108—J. Y. Betts.
- Buttons, manufacture of—1189—G. A. Huddart.
- Cartridge cases, charging and closing—1182—R. A. Brooman.
- Chale cables, manufacture of—624—J. Shorbridge.
- Cranes—884—W. Irlam.
- Croquet, mallets used in the game of—1181—J. F. Feltham.
- Digging machinery—1124—O. C. Evans.
- Driving bands, straps, &c., fasteners for—1223—J. F. Alexander and T. F. Cahin.
- Drying cloths, portable hot rooms for—1136—W. Williamson.
- Dyeing yarns—1193—R. Ferrie, J. Murray, and A. Wilson.
- Electric telegraphs—878—H. W. Cook.
- Electric telegraphs—960—A. Millar.
- Embossing presses—1224—R. Fenner.
- Fibrous substances, preparing and spinning—1160—W. Oxley.
- File blanks, apparatus for rolling or shaping—1190—E. McNally.
- File cutting machines—1172—J. Dodge.
- Fire-arms—1207—E. Della-Nocce.
- Fire-arms, breech-loading—1177—J. Carr.
- Fire-escapes—1164—T. D. Whitehead.
- Flowers and leaves, arrangement of—1187—T. C. March.
- Fluids, apparatus for raising—1191—J. Bernard.
- Furnaces—1186—D. Simpson.
- Furnaces, smoke-consuming—1162—R. A. Brooman.
- Gas ammoniacal engines—1074—L. de St. Ceran.
- Gas engines—986—P. Hugon.
- Gas regulators—1109—F. Wise.
- Guns, breech-loading—1197—L. W. Broadwell.
- Hydraulic pulling jacks—1176—J. Tangye.
- Invald carriages—1120—H. E. Newton.
- Jacks used when roasting and baking—1106—W. Robinson.
- Knife cleaning machines—1213—J. C. Davis.
- Letter clips, &c., manufacture of—933—T. Corbett and R. Harrington.
- Liquids, measuring the flow of—1160—T. Walker.
- Liquids, steam, and gases, valves for—1226—T. Russell.
- Locks and lock furniture—1194—W. H. Tucker.
- Looms, pickers for—1200—G. P. Dodge.
- Looms, self-acting temples for—1142—C. and G. Eastwood.
- Lubricating friction surfaces—1176—J. W. Lowther.
- Machinery, regulating the power and velocity of—1228—C. W. Siemens.
- Mangles—1217—W. Watts and J. Cooper.
- Marine steam engines—1212—D. Hankin.

- Masts, spars, &c., machinery for cutting—1179—S. Harvey.
- Metals, compositions for preserving—1154—J. N. Brown and T. D. Clare.
- Metals, furnaces for smelting and melting—1183—W. Balk.
- Metals, machinery for moulding—1172—R. Canham.
- Metal tubes and rods, finishing and polishing—1229—T. Allcock.
- Motive power, apparatus for acquiring—1158—C. Jacquelin, jun.
- Needle guns, breech-loading—1146—J. F. C. Carle.
- Pencils, overpointed—1216—W. E. Wiley.
- Penholders, manufacture of—1236—M. H. Beguin.
- Petroleum, illuminating apparatus for burning—1237—P. A. le Comte de Fontaine-moreau.
- Pig iron, manufacture of—1208—H. Bessemer.
- Propelling vessels—1216—M. W. Ruthven.
- Reducing friable substances to powder—1178—H. W. Wood.
- Resinous gum or balsam—1173—G. T. Bousfield.
- Revolving shafts, apparatus for receiving the thrust of—1234—E. T. Read and J. B. Pye.
- Rockets—1103—W. Hale.
- Rocks and minerals, excavating and blasting—1192—J. Barnard.
- Sewing and embroidering, machinery for—1187—G. Mumby.
- Sewing machines, guide applicable to—1047—F. Bapty and E. B. Sayers.
- Ships, fastening wooden planking to iron frames in—1162—W. Hubbard.
- Sick or infirm, administering nourishment to the—1140—W. R. Gelp.
- Spectacles, opera glasses, &c.—1206—J. Gutmann.
- Steam engines, double cylinder—860—J. Cooke.
- Tablets, tickets, &c.—1196—C. Gammon.
- Textile substances, ascertaining the degree of torsion and resistance in the threads of—1236—P. A. le Comte de Fontaine-moreau.
- Thrashing machines, fan or exhaust for—1241—W. E. Gedge.
- Utilising the heat of steam, apparatus for—864—D. E. Blacke.
- Vegetable and animal substances, apparatus for disintegrating—1188—F. D. P. J. Cabasson.
- Violet coloring matters, obtaining—1098—E. Smith and C. Sieber.
- Water-closets, indicators and fastenings for—1096—H. K. Taylor.
- Waterproof fabrics—1219—W. E. Newton.
- Water wheels—1189—A. C. Henderson.
- Wood, planing and moulding—1143—J. Robinson and J. Smith.
- Yarns and threads, bleaching and dyeing—118—L. Gaanert.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

- Fog signals, apparatus for producing—1256—E. Richardson.
- Printing types, machinery for setting and distributing—1271—W. Clark.
- Regulating distances, engines and tools for—1245—W. F. Stanley.
- Textile fabrics, drying and stretching—1233—G. T. Bousfield.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

MAY 31.—*Derby Day*.—No MEETING.

JUNE 7.—*Extra Meeting*.—"On the Policy of an Amalgamation of the Railways of the United Kingdom, under Government Management." By WILLIAM HAWES, Esq., Chairman of the Council.

CONVERSAZIONE.

The Council have arranged for a Conversation on Wednesday, the 14th June, at the South Kensington Museum, cards for which will shortly be issued.

INTERNATIONAL EXHIBITION OF 1862.—JURY REPORTS.

The Council beg leave to announce that there are a small number of copies remaining of these Reports, which may now be had on application at the Society's House, price £1 5s. in cloth, or £1 11s. 6d. bound in morocco.

Proceedings of the Society.

TWENTY-FOURTH ORDINARY MEETING.

Wednesday, May 24th, 1865; W. Hawes, Esq., Chairman of Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Hawkins, Henry, Wallingford, Berkshire.
Holroyd, Edward, Church-street, Wimbeldon, S.W.
Miller, James Gordon, Financial Insurance Company, 60, King William-street, E.C.
Payne, Wyndham, 32, Kensington-square, W.
Smith, Thomas Roger, 57, Strand, W.C.

The following candidates were balloted for and duly elected members of the Society:—

Homan, Julius, 85, The Grove, Camberwell, S.
Hunt, Alfred Terrett, 1, Encombe-terrace, Wandsworth-road, S.W.

The Secretary called attention to a peculiar kind of slow-burning fuel, described at page 469.

The Paper read was—

ANCHORS AND CABLES; THEIR HISTORY, VARIETIES, AND PROPERTIES.

By THOMAS MURRAY GLADSTONE, C.E., Asso. I.N.A., Engineer to Lloyd's Registry of British and Foreign Shipping.

The ground tackle of ships is a subject of no mean importance, and comes next to the construction of the hull itself. It has had the attentive consideration of the nautical man as well as of the scientific inquirer throughout all ages of history, its improvements commencing with the first dawn of civilisation. When we trace the history of anchors and cables, we can observe the clear advance of human intelligence, and we also cannot fail to find traces thereof of a retrograde nature among mankind at different epochs. These form certain strongly-divided landmarks, which are made to appear in the course of this investigation. If we take the records of the Chinese, we are given to understand that in the earliest period of their history, from the trading character of their people, anchors and cables (it is true of a primitive character) were known. Though their records can hardly be exactly ascertained as to their approximate dates, yet they show, most decidedly, the antiquity of the use of ground tackle by a people, whole villages of whom live upon the water. Whether the anchors were wood, loaded with stone, or wood, bound together by some metal and weighted, of the crudest form; whether the cables were most rudely put together with the fibres of grasses, or however uncouth and peculiar, they formed the first step in human progression towards the means of navigation. On the other hand we have historical records, both as regards anchors and cables, in the more western world, upon which great reliance can be placed; and as the subject naturally divides itself into two parts, that of the anchor and the cable, as a matter of precedence I will commence by a brief historical account of the anchor.

The anchor being of such vast importance in navigation, from its complicated and weighty character, the want of it must have occasioned the utmost obstruction to the navigator, for it became a necessity on mankind venturing, after constructing larger vessels than canoes, to extend navigation to the coasts. They then found it imperatively needful to have some means that would give security to their ships, when exposed to either a lee-shore or to strong currents. The most ancient consisted of large stones, sacks filled with sand, or logs of wood loaded with lead,

the last of which may even now be seen as used by the Chinese in securing their unwieldy junks. Of this kind was the anchor of the ancient Greeks, which, according to the accounts given by Polonius Rhodius, and Stephen of Byzantium, was made of stone; Athenæus states that they were sometimes made of wood and loaded with stone. It was found that, as these only retained the vessel by their friction on the bottom of the sea combined with their inertia, other contrivances became necessary for the purpose; therefore, as early as iron could be made available, it was introduced for their construction, and then began the grand improvements in forming them with teeth or flukes, by which to fasten themselves in the ground. Thus the words *odontes* and *dentes* are frequently applied to anchors by the Greek and Latin poets; but the general term used by the Greeks for anchor is *αγκυρα*, which Vassius thinks is derived from *αγκη*, a hook or crook, an instrument of iron used for holding ships in any situation, by preventing them drifting on to the shore or rocks; this being effected when the anchor is let down from the ship and fixes itself in the ground so as to hold the vessel fast. The invention of the teeth is ascribed by Pliny to the Tuscans, but Pausanias gives the merit to Midas, King of Phrygia. Originally there was only one fluke or tooth, but, shortly after, a second was added, according to Pliny, by Eupalius, or, according to Strabo, by Anacharsis, the Scythian philosopher. The anchors with two teeth were called *αμφιβολοι*, and from ancient monuments they appear not to be dissimilar to the old Admiralty anchor as used until a very recent period of modern history.

It would appear, therefore, that anchors were generally made of iron through many ages; but in Spain, and in some other parts of the world, when that metal was not available, they were made of copper, and, in the South Seas, of a heavy wood, called "iron wood," from its great specific gravity. Anchors are mentioned in only two places in the Holy Scriptures. The first by St. Paul, when he and his companions were shipwrecked. On fearing they should be cast upon the rocks, "they cast four anchors out of the stern" (Acts xxvii., 30 v.), and in his Epistle to the Hebrews (vi., 19 v.) the same apostle, having no doubt a vivid recollection of his danger, uses it as an illustration when he says, "Which hope we have, as an anchor of the soul, both sure and steadfast." It would appear that, even at this time, vessels had numerous anchors, the largest of which corresponded with what is now denominated the "best bower," or "sheet anchor." This was never used but in extreme danger, and hence was peculiarly termed *sepa*, or "sacra;" thence the expression "Sacra anchora," as indicating the last refuge. Indeed at this time, for want of a proper instrument, such as I proposed in a paper given in the volume for 1863 of the Transactions of the Society of Naval Architects, along with the drawing which would enable us to know what strain a ship exerts upon her ground tackle in all weathers, we have not attached to every vessel that "sacra anchora" so justly venerated by the ancients.

As the sizes of vessels increased, and the working of iron in large masses was still difficult, it can be readily imagined how costly the anchor must have been; so that through many ages that which is so commonly used in moderate-sized ships of the present day, and so economically manufactured, would have been worth its weight in silver; indeed, would have been thought one of the wonders of the world.

The modern improvements are exemplified in the numerous drawings now before the meeting. The first which connects the ancient with the modern times is the old Admiralty anchor, contrasting which with the new Admiralty anchor, it will be seen what a decided improvement and increased beauty of form is reached. Besides these we have a great variety of anchors, the designs of many inventors. When I note that upwards of 80 patents have been taken out for anchors within the last century, it gives strong evidence that a large amount of ingenuity

has been exerted towards attempting to perfect this valuable instrument. Among these I will give a few illustrations from those that best deserve consideration, including those which from their intrinsic merits have become, and are generally used, at this day.

These useful anchors divide themselves into three distinct kinds, each having its peculiar merits, and each having its supporters among nautical men. The first is that which I have alluded to, the "Admiralty anchor," which includes, as a class, all anchors with a "solid cross" or "crown," that is, Mr. Perring's improved Admiralty anchor, Captain Rodger's, Captain Hall's portable anchor, Mr. Cotrell's improved admiralty, Mr. Hutchin's, and other solid crowned anchors. The second is the "pivot" anchor, beginning with Mr. Porter's—Mr. Trotman's, and Mr. Wood's, being of the same class and based upon the same principles. The third is that of Captain Hawkins, of which Mr. Martin's is shown in a great degree to be a modification.

Of the first class it is reasoned, that being of a solid form throughout and less complicated in workmanship, it is, whether as the Admiralty or as Rodgers's anchor, the most reliable for general use. But it is evident that, under one circumstance at least, it has this disadvantage, that as in shallow water the upper fluke of the anchor points upwards from the ground, the vessel is liable to be injured by the anchor piercing her bottom. It will easily be seen that in the anchors of the No. 2 and No. 3 class this liability does not exist. On the other hand it is given as an argument against these other forms of anchors, that in the parts which are jointed they are likely to become fixed by stones or other material of the ground, so as to prevent the arms from taking the proper direction for holding the ship.

Another disadvantage of pivot anchors was said to be that when the ship veered from the direct line of strain in which the anchor lay, it had a tendency to destructiveness from the arm slipping from off the shank, and this weakness is obviated completely in Mr. Wood's anchor by an indent on the shank, making such liability impossible. It is seen that Capt. Hawkins' and Mr. Martin's anchors hold by both arms, and not as the others, by one only. It would appear that these give all which an anchor requires, yet it has been asserted that these are not perfect, and their holding power not certain when the ship swerves from the straight line, being apt to trip. If these opinions be correct, the perfect anchor has not yet been produced; there is, therefore, a field for inventors to work in not yet exhausted. But it is a satisfaction to know that so great has been the attention and care in the proportions and manufacture of anchors, that a very high condition of security is given in the use of these most valuable descriptions.

To ascertain one great necessity in anchors—that of strength—some test becomes necessary, so as to secure the full results of these qualities according to their character and design. This test is by tensile strain, the mode of applying which I will describe further on.

The following table gives the tensile strain of the most distinguished anchors, and sets forth their extreme value:—

ON THE RELATIVE POWERS OF THREE KINDS OF ANCHORS AS TESTED BY A SPECIAL COMMITTEE IN 1851.

	Admiralty Proof.			Cracked at			Break at		
	cwt.	qr.	lb.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.
Admiralty ...	20	2	0	21½	48	56½	73½	73½	73½
Rodgers	19	0	8	19½	45	54½	70½	70½	70½
Trotman's ...	21	1	10	21½	51½	58½	75½	75½	75½

Showing Rodgers up to final separation 27½ per cent. beyond Admiralty test; Trotman's ditto, 143½ ditto; Admiralty ditto, 160 ditto; although Trotman's exceeds the others up to the point of an appearance of weakness.

I now proceed to examine the other branch of this interesting subject, namely—cables. This can be distinctly separated into two parts, the one class being

made from fibrous and vegetable substances, the other being made of metal. For a given period, up to the commencement of the present century, the former was the sole substance of which the cable was made. This was chiefly the direction in which Russian hemp was largely consumed, as, from the smallest line of the thickness of a quill to the largest cable, sometimes even 26 inches in circumference, it was used; but, like all vegetable substances, it was subject to decay. Coir rope also began to be used. Tar was employed to help its preservation, yet its duration was very limited; besides, it was readily chafed by harder matter, so that it became a constant employment for the seamen to save the rope by gaskins, whether at its attachment to the anchor, the pressure at the hawspipe, at the windlass, or elsewhere, which abrasion added not a little to the cost of maintenance with relation to the general charge of the ship. For warping, and for other purposes where comparative lightness is desirable, ropes composed of these substances are still in use, but the disadvantages of rope in the form of a cable for holding the ship were found to be very great; its great bulk, its rapid deterioration from the action of damp, its liability, in despite of every precaution, to be abraded on rocky ground, its certainty of being cut in a tideway by the action of ice, and its greater cost compared with the iron cable, even at extravagant prices—these were more than equal to the advantages arising from its greater elasticity and lightness, so that, for 30 years past, rope cables have been quite superseded by those made of iron.

When first I considered this subject with relation to the second part, that is "iron cables," I believed these to be an invention within my own lifetime, but on looking into the Patent Office, I found that in 1606 there was a patent taken out for chains, the terms of which were very quaint, but practically clear. I thought this was going a great way back, but searching further I found, from an old manuscript in the British Museum (a most valuable and highly illuminated work), that in the 14th century chains were used on board ship instead of hemp. Nor can the fact be questioned, as in a drawing in the same M.S. the ships are moored to the beach by chains, the links themselves being shown. But searching still further—in Cæsar's account of his Gallic wars, about 57 years before the Christian era, these remarkable observations are made by that conqueror, when writing of the Veneti of Brittany. "These people," he says, "trading with the Ancient Britons, called Belge, (who inhabited that portion of England which would include Somersetshire, Cornwall, Devon, and all the south-west of England and Wales) used cables made of iron instead of rope." Now, this singular fact, emanating from so old and excellent an authority, suggests many reflections as to what must have been the condition of the iron manufacture here, and shows it to have been one of the early productions of Great Britain. It points out that nearly 2,000 years ago, in addition to copper, tin, lead, and other metals for which the Phœnicians and other eastern nations traded with Great Britain, the most intrinsically valuable of all of these metals, iron, must have constituted an important item of the industry of the people, and almost makes us think that there must have been a considerable amount of practical mechanical knowledge diffused among the people. The term barbarian must, therefore, be taken in a very modified sense when used by their invaders and conquerors, the Romans, on being applied to the people of Great Britain.

Iron cables were re-introduced early in the present century, and in 1808 Lieutenant Brown, afterwards Admiral, became actively engaged in developing the use and advantages to be derived from them. At the same time, if not earlier, Mr. Robt. Flinn, of North Shields, seems to have been promoting their manufacture, and the following advertisement given in the *Newcastle Courant* of that year, proves his enterprising spirit:—"Notice to Ship-owners. Robt. Flinn, black and whitesmith, North Shields, respectfully acquaints

shipowners and the public that at this period, when hemp can scarcely be procured, he manufactures chain hawsers for ships, of any length or size. The ship *Ann and Isabella*, Mr. Donkin owner, was the first to make trial of a chain hawser, when it was found to answer exceedingly well, both as a bower in Shields harbour, and as a mooring junk in the Pool." My informant also remembers hearing the story that in this year, when the ice cut all the ships in Shields harbour adrift, the *Ann and Isabella*, being moored with a chain hawser, was the only one that rode in the stream safely, so that after that a great demand sprung up for chain hawsers or cables.

According to the account of Mrs. Fawcus, the daughter of Mr. Flinn, Lieutenant Brown got the idea from her father for making cables and hawsers of chain, and on his trying to prevent Mr. Flinn from making chain cables and hawsers, the issue proved that the latter had made them before the former.

It is curious to observe the prices which prevailed on this introduction of iron cables, being no less than 74s. 8d. per cwt., when better proportioned chains of the best material are obtained at this time at 15s. per cwt., or one-fifth of the former cost.

The scarcity of hemp which is noted in the above advertisement was occasioned by that great attempt made by Napoleon I. and the Emperor Alexander of Russia, by a compact between them to exclude all the products of the Continent from entering into Great Britain, the products of Great Britain to be also excluded from the continent of Europe. But this could not be permanent, and was of short duration, though tried by these two mighty autocrats, while even such an attempt at the subversion of the free interchange of commodities, no doubt contributed to the introduction of chain cables by increasing the price of hemp, and thereby stimulated our iron industry, the manufacture of iron being at a low ebb in this country at this time, both in quantity and quality. As proof of this, even within my recollection it was considered necessary to use foreign iron to a considerable extent in the manufacture of anchors, from the indifferent quality of English iron. For any iron work that required great manipulation foreign iron was almost solely used. As an illustration of the backwardness of that now most prominent and important production of native industry, it was subsequently to the year 1820 that even hoops were made of English iron. Previously the iron was imported for this purpose from Sweden or Russia in bars, and converted into hoop iron at several water mills situate on the tributaries to the River Thames.

Such being the difficulties, the early manufacturers of chain cables must either have had the iron specially made for them, which is most likely, or their manufacture of chains must have been very inferior and not dissimilar to many that have been manufactured of late years, the last so indifferent as to have demanded legislation thereon.

It appears that the ordinary chains first made were close links, but shortly patents were taken out for twisted and stud links. The twisted link soon passed away, and the short and stud link remain to the present time as the two conditions in the manufacture of iron cables. The action of the stud was to prevent the collapsing of the sides of the links, to which a chain has a tendency at extreme pressures; therefore, the stud link is commonly used for cables. The ultimate actual strength of the two is found to be nearly assimilate, and I am almost inclined to doubt whether the short link should not be preferred for cables, seeing that if, by any extraordinary pressure, any portion of the links should be found to have become rigid from their collapse, the chain would be considered unfit for future use, while in the stud link, although it might have been subjected to an undue strain, no such deterioration could be detected.

Contrasted with ropes, the chain has many advantages. By its weight it aids its holding powers; by its weight it compensates for its want of elasticity; by its weight it assists as ballast, and its want of bulk affords increased

LLOYD'S TABLE, No. 22.—MINIMUM WEIGHTS (EX. STOCK) OF ANCHORS OF UNOBJECTIONABLE FORM AND PROPORTIONS; SIZES AND LENGTHS OF CHAIN CABLES; AND THE PROOF STRAIN TO WHICH THEY ARE TO BE TESTED; AND THE SIZES AND LENGTHS OF HAWSERS AND WARPS.

The length of them to be 90 fathoms each.

MEM.—For Steamers the Anchors and Cables will not be required to exceed in weight and length those of a sailing vessel of two-thirds their tonnage.

* Two of the Bower Anchors must not be less than the weight set forth above, but in the third a reduction of 15 per cent. will be allowed. All Anchor Stocks must be of acknowledged and approved description.

† Unstudded close-link Chains of one inch in diameter and under, will be admitted as Cables, if proved to two-thirds the Test required or Stud-Chains; but in all such cases a short length, not less than twelve links, must be tested up to the full strain for Stud-link Chains.

‡ Persons desirous of using or supplying Chains of a smaller size, and who are willing to submit them to a greater strain than set forth above, may submit their propositions to the Committee.

space on board ship. Its durability is also great, and, with care and proper usage, it will exceed the life-time of any ship.

From the great improvements that have taken place in the manufacture of iron, from the increased skill of the workmen, and from the great attention which experience has tended to give to its manufacture, we have reached a condition with regard to chain cables, when made in the best way, which is all that can be desired, and the proportion of Lloyd's table No. 22 I think affords a very large amount of security for life and property on ship-board, if all these points are attended to.

As quality, however, is of every importance, both in the anchor and the cable, it was found necessary to legislate thereon, in consequence of bad manufacture (cheapness, not quality) ruling; and last year Mr. Laird, the member for Birkenhead, carried his Bill for the "Testing of Chain Cables and Anchors," which Bill comes into effect on the 1st of July next. This is a step in the right direction, while already Lloyd's Committee of Registry had determined not to give the Class A 1 to any vessel whose cables and anchors had not been tested at a public machine approved by them, and also in sizes, lengths, and proportions, in accordance with their table

No. 22. Independent, therefore, of public legislation, besides the public machines at Liverpool, by the activity of Lloyd's Committee, there have been established and are being constructed more than a dozen public testing machines in different parts of the country, and all that are completed are doing excellent service. The scale adopted for the test is that known as the Admiralty scale of proof, and Lloyd's rule is that all cables and anchors must pass such test in a satisfactory manner. As it is necessary to have proper machinery for passing this ordeal, several modes have been adopted for putting on the necessary strain, either by compound wheels, the worm and wheel, or by hydraulic force. From its simplicity, reduced friction, and economic character, the hydraulic power prevails. This power, so valuable for heavy pressures, and so reliable and controllable, has become one of the most important assistants to the engineer, so much so that without it many works of the present day could never have been accomplished.

I recollect, in the year 1860, when standing on the top of one of the tubes of the railway bridge at Conway, North Wales, the weight of which was somewhere about 600 tons, in conversation with the late lamented Mr. Robert Stephenson and Capt. Moorsom, and when the tube

was being lifted equally at both ends at the speed of three feet in one hour by this marvellous hydraulic force, it was remarked—how wonderful, how true, and how controllable was the hydraulic press, and how exactly to be measured by the graduated steel yard.

At any time, with a note from your excellent secretary or other officer of the Society of Arts, I should be happy to show to any of the members the operations at Lloyd's testing house, Poplar, as the proving of anchors and chain cables proceeds daily at that establishment, and has done so for the last two years and a half under my superintendence; the simplicity, exactness, and rapidity with which the process is carried on would, I think, be fully apparent, and, indeed, to the scientific inquirer, would be found to be exceedingly interesting.

As my time is limited, I have thought it better not to enter into further details in one paper, but I shall hope to have the opportunity for doing so on some future occasion, when many material points can be examined which I have not now ventured to touch upon.

In conclusion I append Lloyd's table No. 22, containing the Nos. and weights of anchors for vessels from 50 to 3,000 tons, also the sizes, tests, lengths of chain cables, hawsers, and warps required, the compliance with which is necessary to give the shipowner the A 1 class for his vessel.

DISCUSSION.

Mr. F. A. PAGET said, having given some attention to at least one branch of Mr. Gladstone's subject, perhaps he might be allowed to make a few observations. Mr. Gladstone had alluded to an instrument, proposed by him, for measuring the strain on chain cables. Having carefully examined his plan, he (Mr. Paget) regretted to state that it was defective in every respect. This was the case quite apart from any difficulties as to the application of the proposed instrument. In the first place, it was unprovided with any means for allowing for the friction of its two leather packings. But even disregarding this shortcoming, it lacked the most important requirement of any common dynamometer. What was demanded in an instrument of this kind, was—according to known principles—in this special case, a record of the work done on the cable by the surge of the vessel. Such a dynamometer ought to be able to record at once the force, the motion, and therefore the work. Mr. Gladstone's proposed instrument no more indicated this than was the work done by a steam engine recorded by the steam gauge. What was required was, in fact, the use of an instrument similar in principle to the ordinary steam engine indicator. A band of paper ought to be moved at right angles to the direction of the pull on the cable, and with a velocity of a known constant proportion. This could, in fact, be done by applying an indicator on Bourdon's principle, and leaving the marks of its pencil on a card worked either by the operator, or by means of wheel work, or even in some cases by the sea. Adapted to a cylinder with a piston pressing on a volume of water enclosed in an elastic diaphragm, it was probable that such an instrument would lead to very useful deductions. Mr. Perkins had, it was stated, used very successfully an indicator of this kind, made by M. Bourdon. There was another point on which he regretted to differ from Mr. Gladstone. He had spoken of the exactness with which the process of testing chain cables was carried on at his establishment. The Board of Trade did him (Mr. Paget) the honour, yesterday, while again requesting him to report on the whole question, to communicate that Mr. Gladstone had now adopted levers and dead weight to his machine, and also that he now no longer preferred to test chains and anchors after being blacked. Mr. Gladstone, however, still appeared to think that it was correct to test 75 fathoms at a time. Admitting that there was a difference in the stress at different parts of the length, Mr. Gladstone thought that all irregularity was obviated by the use of the rollers fixed underneath the cable. But he would ask him

whether the roller which would touch and thus support a 2½-inch chain, would also do this for an inch chain? With respect to the supposed proofs Mr. Gladstone had adduced to support his views, it was to be observed that the resistance of iron varied so much that it was only by means of averages, deduced from a very great number of experiments, that the influence of the weight of the cable itself on the test would be apparent. It was an universally acknowledged fact, that any deduction of the kind could only be formed upon a very great number of data. Kinks were also more easily formed in long lengths, and Mr. Gladstone had himself confessed to a case in which "a link pressed crossways against one of the rollers."

Mr. GREEN deprecated the introduction into the discussion of matters not within the scope of the paper, a course which, he said, had been taken by the gentleman who had just sat down.

The CHAIRMAN said it might, perhaps, be doubtful whether the subject referred to by Mr. Paget was strictly within the scope of the discussion, but he always thought it better to allow a certain latitude.

Mr. PAGET submitted that his remarks applied to two distinct subjects introduced in the paper, viz., the principle of testing chain cables, and the special machinery employed by Mr. Gladstone for that operation.

Mr. ROBERT DAVISON thought the objection made to the remarks of Mr. Paget a very proper one, a passing allusion only having been made in the paper to the testing machine employed by Mr. Gladstone. He had seen that machine in operation, and was fully satisfied with its working. He was at a loss to know on what grounds opinions so adverse to that machine could be formed.

Mr. ROCHUSSES regretted that the subject of the materials of which anchors and cables were formed had not received a more extended notice in Mr. Gladstone's paper. In ship-building it was well known that steel was gradually making way, and it would, no doubt, also be ultimately used for anchors, if not for chain cables, from its greater tensile strength than iron. The standing objection at present against the use of steel was its expense, and the enhanced cost of workmanship as compared with iron, particularly in cases where great accuracy of fitting was required. This, however, was not the case with anchors, which could, therefore, be produced in steel at a comparatively moderate rate. The application of cast steel to the manufacture of chain cables was practically impossible, owing to its unworkable properties, and, therefore, they must fall back upon soft puddled steel. It was a fact much to be regretted that the English workman appeared to have a great aversion to the manipulation of steel. It was therefore to be expected that he would interpose all the difficulties he could in the way of welding the modifications of steel which modern science had introduced into our manufactures. The puddled steel to which he alluded was proved to possess a tensile strength double that of iron. Taking the price of iron for these purposes at £8 per ton, steel of the same dimensions could be obtained at from £15 to £16 per ton; adding to that the cost of workmanship, taking into account a little loss at first, they might have steel anchors and cables at about £25 per ton. That being the case, looking to the important functions that were performed by anchors and cables, he put it to the meeting whether we were justified in using a material for these purposes which would bear a tensile strain of only twenty tons to the square inch, when there was another material at hand which was capable of sustaining a tensile strain of forty tons to the square inch; and while railway travellers were protected, in being drawn up inclined planes, by a material equal to a strain of 60 to 65 tons to the square inch, the lives of our seamen were only guarded by a material the resistance of which rarely exceeded twenty tons to the square inch. He believed shipowners, as a rule, were satisfied if they received from the builder a vessel and its fittings which barely fulfilled

the conditions of the class which it represented, and he feared unless the public took up this question of anchors and cables for themselves, that neither under Lloyd's rules nor any other regulations would they have the largest amount of protection that could be afforded in maritime communication.

Mr. LENOX said that in a paper which he read before the Institute of Naval Architects* he had given the history of chain cable manufacture as nearly as possible as it now stood, and he endeavoured to point out the reasons why chain cables, generally speaking, were most disreputable productions. A little liberality and encouragement on the part of the shipowner were required in order to place this branch of production upon the same scale of excellence as other manufactures in this country. With regard to anchors it was pretty well known that they had been a subject of investigation by a great number of ingenious gentlemen, who each imagined that their own form of anchor was the best; but for his own part he believed that no great advance had been made in this direction since the introduction of what was known as the Admiralty anchor. He gathered from the paper that Mr. Gladstone regarded the Trotman anchor as carrying off the palm from all others. [Mr. GLADSTONE said he only enumerated that anchor amongst others.] The table given by Mr. Gladstone showed the results of the well-known Anchor Committee of the Government, but knowing as he did the manner in which their trials were conducted, he had no confidence in the results they arrived at. Mr. Lenox entered into a somewhat lengthened history with regard to various forms of anchors from the year 1820, tracing the subject up to the period of the introduction of the Admiralty anchor, the merits of which he claimed for the firm with which he was connected. Up to that period, he submitted, the anchors in use, both in the navy and mercantile marine, were not of a reliable character, either in form or manufacture. They were originally confided by the Government to contractors, who, in some cases, made them so badly that there was scarcely any union between the arms and the shank. These anchors lasted as long as the elastic material, hemp, was employed for cables, but with chain cables they were found to be all but useless. He had known a ship go out with eight or nine of these anchors, and on her return, after three years, she had scarcely a sound one left. A quantity of those anchors were handed over to him by the Government to be altered, and, if possible, made serviceable. Those which were moderately sound, after he took them in hand, stood the proof, but wherever there was a flaw in the crown, which was the most important part of an anchor, the expense of the alteration was greater than it was worth while to incur. Mr. Lenox passed on to remark upon the anchor known as Rodgers', which, he said, appeared very soon after the introduction of the Admiralty anchor. The trials of the model of this anchor made at the Exhibition of 1851 were, in his opinion, most fallacious. For his own part, he liked the first form of the Rodgers' anchor better than the second, and the second better than the third, although it was asserted that the last was capable of standing any proof that could reasonably be applied to it. He would ask where was the use of having anchors four or five times as strong as the chain cable that was to be attached to them? They wanted an anchor only a little stronger than the cable, and he therefore agreed with Mr. Gladstone that the field was still open for further improvements in this direction. Mr. Lenox then adverted to the difficulties which were experienced in the manufacture both of anchors and chain cables until testing machinery was introduced. The machine for that purpose on his own premises, he said, was the joint production of Mr. Rennie (father of Sir John Rennie) and Mr. Walker, a talented

machinist who acted as his foreman, and that machine he had in use at the present time. It had been employed in the testing of iron of all kinds. The character of that machine was such that the Board of Trade had decided to license it for testing under the provisions of the late Act of Parliament. He submitted that Lloyd's proving apparatus had yet to receive this sanction; whether they would have the good judgment to make it answer the requirements of the Act of Parliament he could not say. He concluded by remarking, that as long as he remained a manufacturer of anchors and cables it would always be his earnest desire to furnish that which could be thoroughly relied upon.

Mr. TROTMAN vindicated the claims of his form of anchor. It had, he said, been approved by an independent committee appointed by the Admiralty to test its merits, and upon its merits he was content to let it stand or fall. He was ready at any time to meet the Committee of Lloyd's with facts, and he challenged the investigation of the scientific world on the subject of his anchor.

Mr. C. F. T. YOUNG remarked that notwithstanding the condemnation which had been passed by Mr. Lenox upon Trotman's anchor, he understood that gentleman was at the present time making a number of them for the Admiralty; and it was a curious fact that if those anchors were so bad the Queen's yacht was provided with them. With regard to the Martin and Hawkins' anchors, they appeared to be very much of the type of a hundred years back. On the subject of testing he would say he believed there were grave objections to Lloyd's machine, and that it gave fallacious results. He considered that the safety of our marine demanded the most stringent rules on the subject of the testing of anchors and chain cables.

Capt. RODGERS, R.N., said with regard to the experiments with his anchor at the Exhibition of 1851, they must speak for themselves. Mr. Lenox should have stated the weights respectively of the models experimented upon. The model of the Admiralty anchor weighed 24 lbs., including the stock, while that of his own anchor weighed only 18 lbs., also including the stock, and that difference of 6 lbs., put into cwt.s., amounted to something considerable. He had devoted a long life to the study of anchors, theoretically and practically, and his first patent was dated in 1819. He admitted that was a total failure. He had now reached his seventy, and he hoped his last patent. He scarcely knew anything which was really so little understood as an anchor. He had rarely met a man who did understand the principle of the anchor, and it was only after fifteen years unremitting study of the subject that he believed he understood himself, and even now he was not quite sure he did. He had lately ascertained that three manufacturers in the north, who were licensed for his patent, had made fewer than 12,200 of his anchors in the last three years. Having detailed the experiments made with his kedge and bower anchors in competition with the Admiralty pattern, Capt. Rodgers, in conclusion, remarked that he had hoped to have heard a criticism upon the properties of the different forms of anchor rather than a history of their introduction.

Mr. THOMAS GRAY said, Mr. Gladstone had evidently given this subject great consideration, and had written a very clear paper upon it, for which he personally felt much indebted to him. The discussion, however, he somewhat diverged from the original purpose of the paper. Mr. Lenox had favoured them with a chronological history of patent anchors from the earliest times. He had also explained clearly the various alterations effected from time to time in the Admiralty anchor, of which, in its present form, he thought so highly; and had then gone on to show that his testing machinery was, in his own opinion, better than others. It was on this subject that he (Mr. Gray) wished to say a few words. Mr. Pugh had to-night taken exception to the testing in lengths of 75 fathoms, which seemed to be the capacity of the

* Trans. Inst. Naval Architects, Vol. i., p. 160.

machine at Poplar, designed (as both Mr. Gladstone and Mr. Dunn had informed him) by Mr. Gladstone himself, manufactured by Mr. Thos. Dunn, of Manchester, and now known as Lloyd's testing machine at Poplar. Now he would say that that machine was almost universally condemned by anchor and cable makers in the country; and that was the machine they were invited to inspect as a model for the simplicity, exactness, and rapidity with which the work was executed. The peculiar claims alleged in behalf of this machine were that it tested in 75 fathoms lengths instead of 15 fathoms, that it did the work in less time than other machines, and did it better. But, unfortunately (if it did so), anchor and cable makers generally had no confidence in it; whether they were right or wrong in this it was not for him (Mr. Gray) to say. In the testing of 75 fathoms length Mr. Gladstone's rule was that the tensile strain itself with the tapping of the hammer was a sufficient testing. [Mr. GLADSTONE—No, no.] If he were wrong he would rely on Mr. Gladstone to set him right. At all events, the main testing was by tensile strain alone. The test insisted on at Birkenhead and at other public machines of reputation was a tensile strain applied to 15 fathoms lengths, and a subsequent searching examination of each link by two pairs of eyes. The testing strain was applied at Birkenhead before the chain was "blackened," whereas Mr. Gladstone tested "blackened" chains. This was objectionable, as the heat evolved by the strain might cause, and in many cases did cause, the blacking to fill up a flaw in the iron and render it imperceptible. In the next place the machine at Poplar relied mainly upon its hydraulic cylinder, and connected with that cylinder there was a plunger which communicated with a graduated lever for indicating the pressure in the cylinder; but it had been held by the most competent authorities, and could not be controverted, that that was not a correct method of indicating the strain put upon the chain; whether it indicated the exact pressure in the cylinder was indeed an open question. What he most congratulated Mr. Gladstone on this evening was, that he had to some extent apparently seen the error of his ways, by having the lever apparatus added to his machine, so as to put it as nearly as possible on a par with Mr. Lenox's machine, the chief difference being, that Mr. Gladstone's tested in 75 fathoms lengths and Mr. Lenox's in only 15 fathoms. Mr. Gladstone having come over so far, might, he hoped, go yet further, and, when he saw the necessity for it, would probably reduce his machine to 15 fathoms. He hoped that should he have the gratification of hearing Mr. Gladstone read his next paper, after making further alterations in his proving house, he should have the pleasure of agreeing with him, instead of—as he now had the pain of—disagreeing from him.

Mr. GLADSTONE, in reply upon the discussion, said he could assure the meeting it gave him great satisfaction that he had had an opportunity of listening to the opinions of various gentlemen on this subject, so that if he was wrong he might be set right. He did not, however, admit that he was wrong, and, as his views had been shown to be correct by disinterested engineers of high standing, he must hope that he should have the gratification of hearing from Mr. Gray next time they met a confession of the error of his ways, and an admission that he (Mr. Gladstone) was right. He quite understood the point that was raised by Mr. Paget's opening remarks, viz., that he had seen reason not to trust to the hydraulic machine as a sure indicator of power. He confessed he had heard Mr. Gray's criticism of the machine in question with some amazement, for though it was true that gentleman and Mr. Galloway came to see the machine at Poplar, they neither took any account of the dimensions of the parts, nor carefully ascertained its operation; and the plunger—that was a small piston—spoken of by Mr. Gray, was not on the top of the hydraulic cylinder at all, but many feet removed from it. It had been stated that this was a machine of his (Mr. Glad-

stone's) own designing, but it was made by Mr. Dunn, whose plans he approved of as Lloyd's engineer, and it was his office to see that the work was done well; he pointed out, however, what he thought would be an improvement, viz., the extending the test from 15 fathoms to a greater distance. Differences of opinion seemed to have recently arisen as to this machine, judging by a report sent to the Board of Trade, "that the ordinary mode of measuring by the hydraulic lever is liable to great variations from circumstances entirely beyond the control of the person working the machine, therefore not to be relied upon." The machine was represented as being inaccurate; it was also stated that the process and principle that he adopted was wrong, viz., that instead of being confined to testing fifteen fathoms, which had never been exceeded up to that time, at Lloyd's machine they were enabled to prove all intermediate lengths up to seventy-five fathoms, and the following curious statement was made that, when a 15 fathoms length was tested the chain was stretched perfectly tight like a string on a violin, but in the 75 fathoms length the chain was never pulled out of the form of a curve, or rather a series of curves or festoons. It was still more curious, that those who made this report should never have measured the deflection in a single 15 fathoms of chain when under test alone, and also measured the deflection when more lengths than one 15 fathoms were under test, as, had they done so, they would have found no difference whatever between any one of the 15 fathoms at the Admiralty proof. In order to prove that the extended length could be equally well used, at Lloyd's machine there were placed powerful levers, with knife edges, constructed by the eminent firm of Messrs. Maudslay, Sons, and Field, in such a manner as to apply them either at 15 fathoms lengths, or at the more extended lengths, when they were found to coincide with the hydraulic lever in both situations simultaneously. When several lengths of large chain were at the Admiralty test, the deflections between each fifteen fathoms were carefully measured by Mr. Field and Mr. Crosland, and they were found all equal, each deflection being $1\frac{1}{2}$ inch only, or 3 in 2,160 inches; therefore, how it was conceived that they hung in a series of curves or festoons he could not possibly imagine. Certain other experiments were made which proved most completely that whether at fifteen, thirty, forty-five, sixty, or seventy-five fathoms, the strain was perfectly equal throughout the whole, therefore the plan adopted by him for Lloyd's Committee proved itself to be correct in principle and practice, while its economy was obvious, since by the ordinary mode of testing for the complement of a single ship's chains, viz., 300 fathoms, it took twenty proofs, while at Lloyd's machine it took but four or five, and as it only took two or three minutes to put seventy-five fathoms of the largest chain in the machine, and two or three minutes to place it on the examining bench by such contrivances as he had invented and applied, it would be obvious how greatly increased must be the economy and despatch in the operation. He should regret indeed, therefore, if any obstruction were thrown in the way of that which had been decided by disinterested parties to be a great improvement. Mr. Lenox had stated that his machine was worked by hydraulic power at one end and by lever power at the other, but Mr. Lenox had no means of measuring the proportionate exactness of his levers. Lloyd's Committee declared they were satisfied with the test of their machine, and they said if it was not satisfactory to the public, let three eminent practical men, like Sir W. Armstrong, Mr. Fairbairn, and Mr. Penn, investigate the question, and declare whether he (Mr. Gladstone) was right or wrong in the principle he contended for. Mr. Davison, who had experimented on this machine, stated that there was no differential variation whatever at any of the distances. Mr. Lenox had complained that he (Mr. Gladstone) had omitted to mention a great many other anchors that had appeared. If he had mentioned

all he would have had to include a list of at least eighty patents. He considered the remarks of Mr. Lenox as to swivels in chains very valuable. In his paper he had given a brief notice of the leading forms of anchor, without comment of his own, leaving each form to stand upon its own merits. He had been much interested by the discussion, and he trusted that on a future occasion he should be allowed the opportunity of extending this interesting and important inquiry.

The CHAIRMAN said he had now to ask the meeting to express its thanks to Mr. Gladstone for the interesting paper he had read. They must all admit this subject to be of great importance, and one to which a society of this kind could never regret having devoted an evening. The practical object doubtless was to get a good anchor and a good chain cable; but he apprehended that achievement would not be promoted either by patents or by Government patronage, for most of the observations they had heard that evening tended to show that nothing that had yet been done in this direction had been influenced by the privileges conferred by the patent laws or by the patronage of the Government. After all, the most efficient means of obtaining the best thing was to trust to competition among the manufacturers of the country, the stimulus of which would induce them to bring the utmost amount of science and skill to bear on this important branch of manufacture. There was also a further question, whether, considering the vast amount of private property at stake, it was desirable for the Government to interfere to require a proper testing of these cables and anchors. What had been the result of the step taken so far? An act was passed within the last twelve months requiring that all anchors and cables should be tested, and now they found those most interested in the question disputing as to the reliability of the testing machines employed. When the Government system of testing was in full operation, would they be much nearer in arriving at the best anchor than they were now, by going to those whose manufacture had proved to be the best? They had much better rely upon themselves, and the more they threw upon individuals interested the responsibility of providing the best machinery for carrying such works into effect, the better it would be for all parties. In the paper the fact was mentioned that during the great war Napoleon threw such difficulties in the way of our obtaining hemp for our cables that we were compelled to seek for a substitute in the shape of iron. He (the chairman) could not but contrast that period and the conduct of the First Napoleon, with the present period and the conduct of the Third Napoleon—a man who was doing all he could to bring into friendly rivalry the manufacturers of both countries, and in every way to promote commercial intercourse between the two nations, a course of policy which, considering the objects which this Society was established to promote, could not fail to enlist our cordial sympathy. He now begged to propose a vote of thanks to Mr. Gladstone for his excellent paper.

The vote of thanks was then passed and acknowledged.

Proceedings of Institutions.

MANCHESTER MECHANICS' INSTITUTION.—In their Forty-first Annual Report the directors congratulate the members upon being able to present an encouraging statement of the past year's proceedings. The fears expressed at the commencement of the year, that the commercial depression under which the district was suffering would continue to affect the attendance in the classes, has happily been only partially realised; the number of pupils connected with the various departments in 1864, in most instances comparing favourably with the number attending in 1863. The attendance at the boys' day classes has been satisfactory, showing a slight increase, with a corresponding improvement in the receipts. An examination

of the students was held by one of H.M. Inspectors of Schools. At the Government Science Examinations, the candidates from these classes have more than sustained the reputation of the school, and have been awarded two silver medals and a large number of prizes. The attendance averages over 200. Nine candidates were successful in the Oxford Middle-Class Examinations. The attendance at the ladies' day classes is not so good as it was in 1863. In 1861 the number of pupils attending was 242. In 1862 the attendance fell to 229, in 1863 to 201, and in 1864 to 181. These classes have also been examined by the Inspector of Schools. The attendance in these classes, which averaged over 200 in 1863, fell to 180 in 1864. The female evening classes have been well attended. The number of pupils in the summer months was limited, but during the winter quarters the attendance has been so large as to render it necessary to remove the class to a more commodious room in the Institution. The number of pupils on the books in the December quarter was 53. In the evening classes for young men there has been a considerable increase in the attendance, which averaged about 300. Mr. David Baxter has continued his gratuitous services as the teacher of the bookkeeping class. The great success of his pupils at the Society of Arts Examination, is evidence of the ability and zeal with which the class has been conducted. In the Government science classes the number of students who have entered compares favourably with that of the preceding year; but, considering the importance of the subjects taught, the attendance must be deemed far from satisfactory. In the examinations of the Department, however, this Institution has been successful beyond any other. Three silver medals, four bronze medals, and more than one hundred prizes were awarded, while several students secured "Honourable Mention." The results of the Society of Arts Examination have already been published. Mr. H. J. Leppoc for the second time placed at the disposal of the directors a prize of five pounds, to be divided equally among those students who should most distinguish themselves in arithmetic at these examinations. The annual social party of the day classes was held in June, and the usual soirée of the dancing class was held at the close of the year. The gymnastic club still continues one of the most popular features of the Institution. The skill displayed by the members at the last assault-at-arms clearly proved that the club still maintains its high state of efficiency. A challenge gold medal has been offered for competition by Mr. G. T. Lund, in addition to a silver and a bronze medal presented by the committee and the members. The billiard club has been eminently successful during the first year of its existence. It has in a very high degree promoted social and friendly intercourse among those who were unable to avail themselves of the other advantages offered in the Institution. The circulation of books from the library has decreased from 32,679 in 1863 to 27,411 in 1864. The directors record with deep regret the death of the chairman of the board, Mr. J. W. Edge, who for very many years had enjoyed the confidence and esteem of the members, as well as of Mr. John Heywood, vice-president. The directors congratulate the members upon the financial position of the Institution. At the commencement of the year there was a balance in hand of £679 7s. 2d., with unpaid accounts amounting to £187 16s. 6d. There is a balance of £998 8s. 4d., with unpaid accounts amounting to £171 9s. The income has amounted to £3,087 6s. 8d. The total number of members is 1,531, against 1,307 in the previous year.

ANGLO-FRENCH WORKING CLASS EXHIBITION.

A meeting of working men was held in the Society's great room (by permission of the Council), convened by the promoters of the above undertaking, on Tuesday evening, the 23rd inst., WILLIAM HAWES, Esq., Chairman of the Council, in the chair.

The CHAIRMAN, in opening the meeting, said that the Council, upon receiving a communication from Mr. Coningsby, the secretary to the committee formed for carrying out this proposed Exhibition, stating what steps had already been taken in this movement, and the success of the preliminary measures both in England and in France, were desirous that the Society should offer every encouragement to the undertaking. For his own part, he (the chairman) felt especial pleasure in presiding over what he might almost call the first meeting which had been held in this metropolis for the purpose of uniting the English and the French workman in friendly rivalry, the object being not so much to prove that the one was superior to the other in any particular branch of art or of manufacture, but to give them an opportunity of showing each other that in which each excelled, so that the workmen of both countries might learn in what direction they should apply their time and talents, so as to produce the most beneficial results to themselves, and the countries in which they respectively lived. It was quite clear that both England and France, from the great intelligence, perseverance, and industry of their people, must necessarily be constant rivals; but it was of the utmost importance that their rivalry should be a rivalry of friendship, and not a rivalry arising from feelings of distrust or national prejudice. He could imagine nothing better calculated to produce a friendly rivalry likely to benefit both countries than this proposed Exhibition. This was a year, certainly, in which such an exhibition might be very appropriately organised, being the fiftieth year of peace between the two countries. That fact in itself was a remarkable evidence of how great a length of time was required to remove prejudice when once it was deeply seated between nations. It appeared to have taken fifty years before the working men of both countries, who formed the great mass of the population, could meet upon terms of peace and good fellowship, and enter into friendly competition with each other. However glad we might be that such a result was brought about at last, we could not help feeling what a melancholy instance this was of the great mischief which followed long and devastating wars, and the great amount of prejudice and ill-feeling which were thus engendered to the great detriment of the world at large, and more especially of those countries where such wars were carried on. Now, however, that these fifty years had passed, we could not but hope that the good feeling between the two countries would increase year by year, stimulated as it was by the enlightened men of this country, as well as by that great man who was now the ruler of the French people. It was remarkable how much had been accomplished by that illustrious sovereign, whose acts had so materially aided the progress of free-trade in Europe. Without that encouragement, which happily the Emperor had not only the will but the courage to give to free-trade and free communication, he (the chairman) really believed the progress which had been made would not only not have been accomplished, but would even now have scarcely been begun. During the Bourbon dynasty there appeared to be little chance for such free communication between England and France as there now was, for he was sure they must all feel that the abolition of passports and the interchange of commodities now carried on under the French treaty were remarkable proofs of the truly enlightened spirit in which the French Emperor regarded questions of international commercial policy, and he had little doubt that the undertaking which they had now met to consider would receive every encouragement from the French Government. He would now call on Mr. Coningsby to explain the steps that had already been taken in connection with this movement. After that some resolutions would be proposed in order to promote the success of the undertaking.

Mr. R. CONINGSBY said he would begin by stating that they did not, however anxious the committee might be to secure the support of all present, now come to ask if this

thing should be done, but only how it should best be done. They were too far committed to it to retrace their steps. The origin of the scheme was something like this. A few friends and himself went to the Agricultural Hall last October, when the North London Exhibition was being held there, with the view of carefully examining the exhibition, so as to see what representation it was of the best productions of the working-classes. Without wishing to depreciate that Exhibition, he must frankly say they could not regard it as a fair representation of what the working classes really could do, and feeling this, they took counsel together whether something could not be done that would give to the section of the working classes not represented there an opportunity of coming forward and showing what they could produce. A committee was formed of about 40, all of whom were working men. There were no patrons, and at first it was decided to have none, that anybody who liked might help the movement, but that the Committee would not solicit patronage. They thought their first step should be to find what amount of assistance they could expect from their own countrymen. Many of the committee-men were foremen in large establishments, and these men talked both with their shop-fellows and employers as to what countenance they would give them. This was done before they committed themselves to the scheme at all, and before calling any public meeting. From inquiries made it appeared that the scheme was likely to take, and the committee had many promises of help, both from workmen themselves and their masters. Those of the members who had friends in provincial towns wrote to them, and found that they received the matter in a very favourable manner. It then came to be a question whether this should be a local movement, or whether they should invite competition from a larger area. It was decided that there was no great use in circumscribing the affair, and, as this year was the fiftieth anniversary of peace between England and France, they thought of making it a jubilee movement, and inviting the French workmen over to compete with them. It was rather a difficult matter to find out whether the French would enter into it or not. The English were ready enough, but they felt some diffidence in going to France as the representatives of English working men. It seemed something like the three tailors of Tooley-street being the representatives of the British people, and they were therefore careful in stating to the French that they merely represented their own committee. Five of them were requested to go to Paris. Their own committee subscribed all the necessary funds, and asked nobody for a penny. They went to Paris, and took a few letters of introduction with them. The idea had been well received here, but when they got to Paris they found that it was received with enthusiasm. Every person they called upon—no matter what his position—whether workman, senator, or manufacturer, gave them the same warm welcome. He was sure every member of the deputation would bear him out when he said that it was quite a mistake to suppose that there was any coldness on the part of the working classes of France towards this country; they had the warmest feelings for us, and he thought that if this matter had stopped here, and had gone no farther, it would be worth all the trouble they had taken to ascertain this one great fact—that there is no ill-feeling or prejudice existing in the minds of our social equals in France towards the workmen of England. They were taken up by a society called the "Société du Crédit au Travail." He believed there was nothing like this society in this country; it was a sort of bank, into which every member put 100 francs, which was laid out in the purchase of land. It was a very responsible organisation, and the deputation were recommended to it by M. Michel Chevalier. This society called a meeting of delegates, representing all the principal associations in Paris, to the number of about eighty. They put a great many questions to the deputation; they did not want to go into the matter at hap-hazard, but wished to know the

grounds of success. They were told frankly what had been done from the very commencement, and given distinctly to understand that they were not there as representing the English workmen, but only their own committee. The meeting passed resolutions approving of the scheme, and, on the spot, appointed a committee of ten gentlemen, well known in connection with the *Crédit Foncier* and other important organisations, and many of them being also chairmen of large co-operative associations. That committee promised to send a circular to each of the departments, and, as three of them were editors of newspapers, they promised to use their influence through the press, and gave every prospect of a wide co-operation on the part of the French people. The deputation called on about five-and-twenty manufacturers, to whom they had letters of introduction, and found that to a man they were all ready to send their goods to the Exhibition. The Crystal Palace had a great name in Paris: people there believed in it, and as soon as they heard that their visitors came from the Crystal Palace they were quite ready to send their goods. M. Edmond Potonié was appointed as the secretary of the French committee, and favourable notices of the movement had been given by the French papers. The French Committee reported that they believed they would be able to send over a large amount of goods, and they were in a position to do this because they had large manufactories there, conducted on principles similar to those of our co-operative institutions in this country—extensive factories, from which a large quantity of goods for exhibition might be expected. The next step they were about to take was to send one of their number to Paris, to watch the interests of the affair, and to communicate between the two committees. The steps they had taken since their return to England might be soon summed up. The Society of Arts, through its Council, had taken up the movement with very great kindness. They had lent them this room for their meeting here, and the Chairman of the Council had been good enough to preside. Their object now was to lay their scheme before the meeting for their approval and assistance, which would be highly valued.

Mr. WHITTING proposed the following resolution:—

"That this meeting, having heard the statement of Mr. Coningsby, in reference to the proposed Anglo-French Exhibition, recognizes in this movement an evidence of the gradual extinction of national prejudices, and of the great advance which has been made by the workmen of both countries in the knowledge and appreciation of the true principles on which the material prosperity and moral progress of nations depend."

He said that one object they had in calling the present meeting was to ask assistance in one department of the proposed Exhibition, namely, that of Art-workmanship. There could be no doubt that in the working men's exhibitions which had already taken place in London art-workmen had not been fairly represented, and it was very important that they should be in the present one.

Mr. WILLIS seconded the resolution.

Mr. LUCRAFT was sorry that he could not support the scheme, not that he did not approve of it, but only because he thought there would not be time to get up the Exhibition in such a manner as fairly to represent the British workman, who would thus be placed in an unfair position. He suggested that the Exhibition should be put off till next year, and that then not only French workmen, but those in all the countries of the continent and of the world should be invited to take part in it.

Mr. ANSON thought the proposed Exhibition was a step in the right direction, and that it would instruct British workmen, and prepare them for future competitions. He felt so deeply interested in the movement that, though not affluent, he should be glad to be responsible, in the case of failure, to meet the expenses to the extent of £5.

Mr. ASH and Mr. BUCK highly approved of the

scheme, and the latter gentleman said he was sure there would be plenty of time before the Exhibition opened for British workmen to prepare articles for show.

Mr. PHARRALL (Secretary of the London Mechanics Institution) congratulated the meeting on the success of the movement as far as it had gone. He believed the Exhibition would form a new and desirable link between employers and workmen, if, as he believed they would be quite willing to do, the masters would exhibit work done in their establishments with the names of the workmen attached to it. English and French workmen had much to teach each other and to learn from each other, and the proposed Exhibition would be an excellent opportunity of bringing them together.

Mr. WINKWORTH strongly supported the principle affirmed in the resolution, and stated his belief, founded on his experience as an adjudicator in the Great Exhibitions of 1851 and 1862, and of the Paris Exhibition of 1855, that English workmen need not fear to enter into competition with those of France. The progress made by the English in the silk manufacture between the two exhibitions was such as to astonish even the French people themselves. He believed the time was fully come when such an exhibition as that now proposed should take place, and that it would be of benefit to both countries.

The resolution was then carried unanimously.

Mr. LOOK moved—

"That this meeting pledges itself to promote by every means in its power the success of the undertaking."

So much had been said in support of the movement that it required nothing to be added to it, but he would suggest to the Committee that they should use their utmost exertions amongst the employers of labour, who were in possession of most of the works produced during the last few years by Art-workmen, and who would, doubtless, be glad to aid in promoting the success of the scheme. It was also necessary, in order that the exhibition might be thoroughly successful, that there should be the fullest confidence in the persons selected as adjudicators of the prizes.

Mr. MAYNARD seconded the resolution, which was unanimously carried.

Mr. R. CONINGSBY moved a cordial vote of thanks to the Society of Arts and to the Chairman, which was carried by acclamation.

The CHAIRMAN said that it was undoubtedly one of the most important functions of the Society of Arts to encourage Art-workmen. Arts, Manufactures, and Commerce were based upon the skill of the workman, and he conceived, therefore, that they were only doing their duty in endeavouring to promote this movement. He had already given them his opinion of its importance, and he would now only tell them what he thought about its success. When Prince Albert attended a meeting in that room previously to the Exhibition of 1851, and some doubts were expressed as to its success, his answer was "Gentlemen, you will succeed because you are determined to succeed;" and the same remark might be applied to the present undertaking. The promoters of this movement had shown so much determination, and had received so much encouragement both here and in France, that there seemed little doubt as to their success. The movement must be a combined one between masters and men: masters must be willing to show their workmen's work, so that the actual producers might have the credit, which had hitherto too often been kept from them. The great value of such exhibitions was the strong stimulus they gave to progress and the promotion of self-respect and honourable feeling amongst workmen. If the masters would not allow the men to exhibit fine specimens of work which they had executed, a great part of the use of the Exhibition would be lost, but he felt sure that the masters would unite in promoting this friendly rivalry between their workmen and those of France. It had been said that English workmen must be beaten in matters of taste by the French, but was taste the only thing that was

required in work, and were there not other qualities of as great if not greater importance? It was a remarkable fact, that so astonished were the French themselves at the progress we had made between the two Exhibitions of 1851 and 1862, that they actually sent over a commission to see by what means we had so improved our art manufactures in the short space of eleven years. The French people had to learn to imitate the solidity and lasting character of our work, and we had to learn the taste and elegance of theirs, so that there was much to learn on both sides, as well as much to teach, and every opportunity of doing this was a benefit to both countries. In conclusion, he would say that they were quite welcome to the use of the Society's room for their meeting. Anything the Society could do to promote the success of the Exhibition would be done. He thanked them for the compliment paid to the Society and himself in the vote just passed.

Fine Arts.

THE DE MORNAY COLLECTION.—The late duke was a liberal patron of art and artists, and his collection of pictures and other objects of art and curiosity is certainly one of the most remarkable that was ever brought together in a period of ten or twelve years. The sale is fixed to commence on the last day of the present month of May, and to conclude on the 12th of June, the first four days being devoted to objects *d'art* and curiosities. The private views take place on the 25th and two following days, and the public exhibitions on the 28th and 29th instant; and, as a large attendance of amateurs and virtuosi is expected, it will be well to give the readers of the *Journal* a general idea of the contents of the collection. M. de Mornay was a great admirer, and considered to be a good judge, of the works of the German, Flemish, and French schools, but he seems to have had little taste for the great Italian masters or for sculpture. Amongst the old paintings of the German, Flemish, and Dutch schools there are:—Three pieces by Cuyp; an excellent little work by Gerard Dow; one of Hobbema's finest works, known as *Les Moulins*, a glowing landscape—a river and mills, and five clumps of oaks, for which the late duke gave 100,000 francs; good specimens of Denner, Dusart, Erverdingen, Helst, Heyden, De Hoogh, and Huysmans; a very fine work by Maas, a robust servant girl ringing at a house door, with three children near; three remarkable pictures by Metsu; an admirable *Miérin*, the itinerant musician asleep in a cabin; three pictures by Ostade; a Paul Potter; one of the finest portraits extant by Rembrandt, a man in the prime of life, wearing a broad-brimmed hat, his face brilliantly lighted up, known as *Le Doreur*, from the Chavagnac collection, as perfect as when it left the artist's hand, signed, and dated 1640; *Europa*, a small composition; and the portrait of an old woman, also by Rembrandt; *Hereules* and *Omphale* and a portrait by Rubens; three works by Ruysdaels; one by Jan Steen; two by Teniers; and three each by Ferburg, Van der Velde, and Wouvermans.—The elder French school includes, amongst other choice works, two fine pictures by Chardin; two of Fragonard's best known paintings; six by Greuze, including his famous *Peasant Girl* winding cotton; three of Prudhon's most admired works—*Innocence*, *Cupid* and *Psyche*, and *Zephyr*; and four good specimens of Watteau.—The contemporary French works include some very fine pictures, amongst which must be specially mentioned the *Ape* painting, by Decamps; six works by Meissonier, including two of his finest productions—*The Braves*, 1852, and *Halt of Cavaliers* at the door of a country inn, 1863, which have never before been in the market; and four exquisite examples of his more usual style—a young man eating and reading; the amateur of drawings; a poet and a young man studying; and three charming works by Alphonse Roehn,

a French artist, who died last year, but whose works recel the best period of the Flemish school.—The Italian and Spanish schools are only represented by five works by Guardi, excellent specimens; two or three by Murillo; two of Salvator Rosa; and two Velasquez.—The collection of objects of art and curiosities consists almost entirely of Chinese and other oriental works in enamel, porcelain, rock crystal, jade, and lacquer, many of which are very choice.

RAFAEL'S FRESCOES.—A Parisian photographer has recently returned from Rome with twenty-seven plates of the frescoes of the Farnese Palace.

MONUMENT TO DANTE.—The inauguration of the monument raised in Florence in honour of the great poet of Italy, took place on the 14th May, with great ceremony, in the presence of King Victor Emmanuel. There was a grand procession, which occupied more than two hours in passing. First marched the representatives of the press (Italian and foreign); next came those of the Italian drama; then a long file of persons deputed from every province, town, academy, society, and important institution in the kingdom. Seven hundred banners floated in the air. The *cortège* was closed by the colleges, the national guard of Florence, in the ranks of which marched the Count Sarego Aligheri, descendant of the poet. The King was received with immense acclamations; upon his majesty's arrival the Gonfaloniere of Florence pronounced a short address, after which Padre Jean Baptiste Giuliani delivered a discourse on Dante and his works, at the conclusion of which the veil which until then had covered the monument fell to the ground. The entire arrangements proved satisfactory, and the enthusiasm is declared to have been indescribable. Such an act of national pride and fervour does honour to the capital of united Italy.

SALE OF ARTISTIC FURNITURE.—The sale of a remarkably fine collection of objects of Industrial Art took place recently in Paris. The articles disposed of belonged to the late Prince de Beauvau, and although consisting of but forty-four lots of furniture, bronzes, porcelain, and sundries, with seven pictures, the proceeds of the day's sale were £14,392. The most precious item in the former portion of the collection was a small secretaire of the time of Louis XVI., presented by Marie Antoinette to Madame Sénoné, one of her ladies of honour, purchased for the Empress at £2,400. A commode, inlaid with marqueterie, and ornamented with chasings in bronze, by Gouthières, the cyphers of Marie Antoinette appearing amongst the ornaments, fetched £1,004. A console, in marqueterie, by a celebrated art-workman, I. H. Reissner, and bearing his signature, of the same period, sold for £828. Two small sofas, or settees for two persons each, fetched £400. A small ebony coffer, decorated with five Florentine mosaics, £118. An inlaid clockcase of the time of Louis XIV., £120. A small bureau of the time of Louis XIII., £122. A carved and gilt bedstead of the Louis XV. period, £162. A cup in Sicilian jasper, mounted in bronze, chased and gilt, by Gouthières, £1,276. Two candelabra, by the same artist, figures of Bacchantes, after Clodion, £644. An inkstand, attributed to the same artist, £232. Two candlesticks, ditto, £166. Pair of fire-dogs in bronze, chased and gilt, time of Louis XVI., £102. Six lots of porcelain fetched £1,872. A jewel-box in copper gilt, bearing the cyphers of Henry II. and Catherine de Medicis, £304; and two vases of porphyry, £644.

Manufactures.

NEW KIND OF FUEL.—A fuel has been invented by Mr. Stoker composed of carbon in powder as pure as possible, obtained from the distillation of light woods in a close receptacle of various metallic salts and acids acting as the combustible matter, and of different agglomerating bodies

such as fecula, &c. The whole is triturated, mixed, and pressed, forming a paste, which may be moulded into cakes, balls, &c., of various sizes, to be afterwards dried. When dry this fuel may be lit by a lucifer match; it burns like a piece of tinder, and gives out neither smoke, gas, nor flame. The caloric disengaged in the burning of this fuel may be from 45° to 720° Fahrenheit, according to the proportion of the different component parts above cited. This fuel (says the inventor) will be found very useful for heating feet-warmers, for urns, dishes, and similar articles, for placing in plumber's soldering irons, or in irons for pressing linen; for heating glue in workshops or elsewhere where a fireplace would be inconvenient or dangerous, and for many other purposes.

NEW GAS FOR MOTIVE ENGINES.—The Motor Lenoir has achieved considerable success, but its application is limited to the supply and cost of the gas required to work it, and it is said that an engineer of Lyons, M. Million, has hit upon an expedient which is likely to have a great effect in extending the use of that or other motors in which power is obtained by the explosion of mixed gases. The problem is to find a gaseous mixture which takes fire easily and rapidly, and which can be produced in almost any place at a low cost. This desideratum is believed to have been discovered in the gases which are given out when steam is made to pass over coke in a state of incandescence, or, in other words, in a mixture composed of oxide of carbon and carburetted hydrogen. The subject has been introduced in a lecture at the Sorbonne, and before the Scientific Association of Paris, by MM. Schloßing and Demondésir, the engineers of the tobacco manufactory, and M. Troost, and has attracted considerable attention. In the experiments performed it was shown that when oxide of carbon alone was introduced into a vertical tube, and fired by a spark from a Ruhmkorff coil introduced at the upper end, a blue flame appeared and slowly traversed the tube until it reached the bottom, and that the introduction of a small quantity of hydrogen accelerated the combustion, and caused the flame to descend with greater rapidity. This was illustrated by a tube more than eighteen feet long. Another experiment showed that when the explosion was caused in a series of vertical tubes alternately connected together above and below, the flame when ascending traversed the tubes more quickly than when descending. The engineers mentioned are now carrying on a series of experiments to ascertain the most economical mixture of these gases with atmospheric air for motive purposes, and success is considered to be almost certain. It must not be forgotten, however, that although the new system may supply a cheaper and possibly more effective motive power, it will have one drawback that does not attach to the Lenoir motor, which can be used in workshops and other places where it would be impossible or inconvenient to introduce a furnace. As steam will be required to produce the gaseous mixture, the new motor will come into direct competition with the steam-engine, which the motor Lenoir does not.

Commerce.

FRENCH TRADE WITH ABYSSINIA.—An expedition is announced to depart from Paris in the month of June, having for its object the establishing of a trade between the natives of Abyssinia and the French merchants in the Red Sea. The spot selected for the head-quarters of the expedition is Mount Taranta, which is not within the possessions of that dangerous monarch, King Theodore, and where the climate is described as being very temperate and healthy. The point of operations on the sea coast is to be Hala, near Port Adulis. The funds are obtained by means of subscriptions from the persons engaged in the expedition, and it is said that the number already enrolled is sufficient to ensure the carrying out of the

project. The projector and leader of the expedition is Count de Moynier, who is half an Englishman, his mother having been the daughter of General William Burn, whose services in India gained him the soubriquet of the Hero of Delhi. Count de Moynier announces in addition arrangements for affording sportsmen a chance of elephant and other shooting in connection with the expedition, which will be armed and organized against any danger from the natives.

Colonies.

ARROWROOT IN NEW SOUTH WALES.—Experiments have recently been made on the root of the Cumbungah, a common reed, growing abundantly in the lagoons of the south-western districts, and possessing, it is believed, properties capable of affording employment to hundreds of persons. An excellent species of arrowroot has been made from this plant.

DOCKS IN NEW SOUTH WALES.—The Fitzroy Dock, belonging to the Government, situate at the penal establishment of Cockatoo Island, is capable of taking in vessels of the largest tonnage. The Waterview Dock is very largely used in docking the vessels engaged in the mail services and those belonging to several local companies and proprietors, and is capable of taking in the largest class of ships. Adjoining are shipwright and engineering works, large shears for masting purposes, and every requisite for the repair of vessels in the several branches to which they apply. The floating dock is Darling Harbour is chiefly used in docking sailing vessels and small steamers. There is a very large establishment formed for making large power boilers and heavy machinery, provided with steam hammers for heavy forgings, large lathes, and all requisite tools for the construction or restoration of engines of large dimensions. The ship dock is capable of taking up separately two vessels of about 1,000 tons each. At these works four iron vessels have lately been built, adapted to the peculiar requirements of short river navigation, one of which was a gun boat built for the New Zealand Government, fitted with shot-proof towers, which has done good service and taken a very prominent part in the history of the present New Zealand war. The vessels are of large dimensions, to ensure a light draught of water.

QUEENSLAND IMPORTS AND EXPORTS.—The total value of the imports for the year 1864 was £2,267,954, of which £1,746,841 came from Great Britain, £506,637 from the other Australian colonies, £7,370 from Germany, £6,880 from South America, £100 from the South Sea Islands, and £36 from New Caledonia. The total value of the exports for the year was £1,243,908, of which £264,437 were sent to Great Britain, £689,368 to the other Australian colonies, £632 to India, £7 to Ceylon, £24 to China, and £4 to South America. The comparison of these tables with those of former years shows the rapid progress the colony has made since 1860. If those who have been induced to settle there had not succeeded in obtaining profitable employment, they could not have afforded the luxuries which have been imported, and the total amount must have been greatly reduced as well as the average per head.

RENTS OF CROWN LAND IN SOUTH AUSTRALIA.—For many years the best pasture lands in the colony were leased at one farthing per acre yearly, until, in 1858, an Assessment on Stock Act was passed, making the payment for rent and taxes together one penny per acre yearly. This was, of course, still far below the value, and as in June of the present year, a large number of the leases expire, the lands comprised therein have been re-valued, and the average rent and assessment for the first batch of the best runs now amounts to about 6d. per acre per annum, which have been confirmed by the Government. Many farmers, however, are paying 1s. and 1s. 6d. per acre to private persons for grazing land.

Notes.

COTTAGERS' EXHIBITION AT AMBERLEY, GLOUCESTERSHIRE.—Some time ago the Rev. R. E. Blackwell, the incumbent of this parish, which has only 1,400 inhabitants, conceived the idea of finding some means by which poor people might be enabled usefully to amuse themselves in the winter evenings without having to leave their houses. The problem he wished to solve was how to find interesting and amusing occupation for the poor man at home during the winter months, and his idea was to get the poor to make whatever articles their taste or inclination prompted them to make, and which would yield them a return when they were sold at an exhibition that should take place at the winter's end. Last October, therefore, he issued a circular addressed to them, in which he said:—"My plan is to try and set all of you—men and women, boys and girls—to work in a pleasant way in your own houses, at your odd moments, during the winter, and for you to gain something by it. At some suitable time in the spring, I should like to have in our school-room an industrial exhibition. During the winter months I would have you all work for this, according to your own different tastes and powers; one making one thing, and one another. Everything you make will be your own. At the time fixed for the exhibition, I will endeavour to gather together our friends throughout the neighbourhood—and sell for you the things you have made, if you wish them to be sold. I do not promise to sell them, but I will try to do so. Let everybody make something, however small or simple. Do not be shy, or hesitate to join our workers. Let every person in the parish be an exhibitor, and try and make something which will do him credit. Great moral benefits must result if we endeavour to spend our winter evenings in a profitable way." Mr. Blackwell suggested what kinds of thing could be made, and during the last six months nearly every cottage has been the nightly scene of work for this exhibition. Men, women, and children have been busy. There has been a curious reversion of labour; for weavers have done carpenters' work, and the industry of others has taken a direction equally strange. The articles made, together with others lent by ladies and gentlemen of the neighbourhood, were recently displayed in the school room. Rugs and quilts, worked with every material and in every colour by the women and girls of the village, draped the walls. The articles of industry comprised vases, plates, and figures, sculptured in freestone; a model landscape; an obelisk in shell work; pencil drawings of cottages and gardens, done by boys; a shapely stone table, with ornamental pillar; a fancy oak table; a model church in stone; a spirit-level; a case of artificial flowers worked in wool; ingenious comic drawings; shoes, slippers, stockings, and other articles of dress. There was an ingenious rat-trap, for which a prize of £1 was given by the Ratcatching Club of London; a well-carved book-stand; a music-stand; and many other articles. The room has been crowded with visitors, and Mr. Blackwell was present to show the articles, most of which have been sold.

Correspondence.

ON THE WEAR AND TEAR OF STEAM BOILERS.—**SIR,**—I have seen Mr. Paget's double-barrelled letter in your last number, and observe there is a deal to be said on both sides of the question; but I shall confine my remarks within a very narrow compass. The essence of my first letter (in your number for May 12th) with respect to the furrowing of boiler-plates is, that Mr. Paget has adopted precisely the same view of the cause of furrowing that I did five years ago, namely, the action of the steam-pressure to straighten, or at all events to make

more nearly straight than before, the common lap-joint, and thus to bring about an alternate bending and unbending of the metal, resulting in a loosening of the texture, and a greater susceptibility to corrosion. Now, I fail to find this central idea enunciated, or even hinted at, in the parallel column in Mr. Paget's letter. The only thing like it is in Mr. Braithwaite's paper, "On the Fatigue of Metals," where he refers to the buckling of locomotive smoke-box plates, in consequence of the strains from the cylinders, which are entirely exterior to the boiler. To this buckling action I alluded in my last letter. Mr. Ranton, to whom Mr. Paget refers, does not in his pamphlet even hint at any explanation of furrowing action. With respect to the pitting of boiler-plates, I stated in "Recent Practice," that—

"The pitting of the metal is readily explained by the presence of chemical agents in solution in the water, and the known inequality of substance of iron plates and bars, in consequence of which the metal is gradually but unequally separated and dissolved."

This, in like manner, is the essence of Mr. Paget's enlargements on the pitting of steam-boilers. In the same book, "Recent Practice" (pages 16, 17), I explained the causes of the failure of the stay-bolts of locomotive fire-boxes in the following terms, which I am obliged to quote for the benefit of Mr. Paget, who has vainly strived, he says, to find the explanation:—

"Copper expands by heat half as much again as iron, and taking the mean temperature of the copper of the fire-box at twice as much as that of the shell, an assumption which, we suppose, is something much below the fact, the vertical expansion of the fire-box would be, upon the whole, three times as much as that of the shell, and the difference of expansion would be twice that of the iron, or at the rate of 1 in 500. On a fire box five feet three inches high, the difference of expansion would at this rate amount to one-eighth of an inch. That is to say, the upper stay-bolts would be deflected one-eighth of an inch from their normal position, when under the power of high pressed steam. On a length of stay-bolt of three inches, a deflection of one-eighth of an inch is immoderate; and considering the alternate expansion and contraction, bending and relaxing, attendant upon getting up steam and letting it down, it is reasonable to conclude that the same cause of degradation is at work with the stay-bolts as that already suggested for boiler-plates at the rivet-joints,—the alternation of strain, tension and relaxation, which loosens the texture, and ultimately overpowers the cohesion of the material so treated, incurring partial fracture and accelerated corrosion. On this argument the failure of stay-bolts should, as in fact it is, be localised at or near their junctions with the plates, which are the points of maximum strain, similarly to the localisation of furrows near rivet joints. Occasionally, entire rows of rivets are found to have snapped across, close to the plate, independently of corrosive action, suggesting a cause of failure precisely the same as that which breaks axles—an alternating lateral strain and relaxation beyond the limits of enduring elasticity."

* * * * *

"The reasons above advanced afford an explanation of the fact that fire-boxes with narrow water spaces are more subject to leakage than those with wider spaces, the stays being stiffer and less flexible in the former case, and likelier to fail. For the same reasons, stay-bolts of smaller diameter, sufficiently strong, are preferable to others of larger diameter. They are more elastic, and yield to unequal expansion more readily than thicker stays, and are, therefore, likely to be more durable."

In fine, Mr. Paget is quite welcome to the use of what I have before published; and, whether he acknowledges it or not, there is no doubt it forms the basis of the greater portion of his paper. Of course he has largely superadded illustrative and corroborative matter, which he appears to have expanded into what he calls the "bulging theory," whereby there is a disposition to convert a cylinder into a sphere. I believe I have said all that is necessary in explanation of my letter.—I am, &c.,

D. K. CLARK.

GRANTS OF PROVISIONAL PROTECTION.

Alarms, self-acting, for indicating excess of heat or cold—1223—J. H. Johnson.

Buildings, construction of fire-proof—1170—J. Cunningham.
 Candles, ornamenting—1299—P. Brash and R. Irvine.
 Corn, &c., apparatus for grinding—1267—J. Hurt and H. Tonge.
 Cotton and wool, presses for—846—W. Miller.
 Cutlery, composition for cleaning, &c.—1054—G. Mountford.
 Cylindrical castings, moulds for—1285—D. Hartley.
 Cylindrical or conical articles, apparatus for cutting—1247—G. Bedrup.
 Decoctions, obtaining—1227—F. Wise.
 Door mats—1283—T. J. Mayall.
 Dredgers—828—W. Simons and A. Brown.
 Extracting copper—1255—W. Henderson.
 Fabrics, elastic knitted or looped—1276—B. B. Cooley.
 Fibrous substances, apparatus used in carding—887—E. & F. A. Leigh.
 Fire-arms, breech loading—1289—J. C. Conybeare.
 Fire-arms, breech loading—1293—P. O'Hagan.
 Fire-grates, &c., supplying fuel to—1259—C. Lampart.
 Fires, self-acting apparatus for extinguishing—1279—J. G. Hay and
 V. Savory.
 Gases and vapours, method of mixing—1287—W. Jackson.
 Grain, &c., self-acting and self-registering machinery for weighing—
 823—T. Roberts and L. Luc.
 Illuminating purposes, apparatus for—1269—P. A. Le Comte de
 Fontenemoreau.
 India rubber, treatment of—1257—T. J. Mayall.
 Iron, apparatus for puddling—1231—T. F. Cashin & J. F. Almadar.
 Jacquard and indexing machines—1261—J. Wadsworth, H. Dwyer,
 and J. McMurdo.
 Malt and grain, drying—1297—J. Forbes.
 Metal, drilling and rivetting plates of—1291—D. Adamson.
 Minerals, apparatus for working or cutting—1203—W. Leatham.
 Motive power, machinery for obtaining—1301—W. J. Rice.
 Motive power, obtaining and applying—1303—S. Pokutyński and M.
 Mycielski.
 Pen, self-supplying—1231—J. Catillon.
 Railway trains, communication between the passengers and guard of
 —1265—S. Trotman.
 Refrigerator and condenser—1249—J. Hampton.
 Saddles, safety stirrup for—1285—S. Hudson.
 Ship compasses—1261—J. Lilley.
 Ships, applying water as a motive power for—1053—G. Roosevelt.
 Ships, &c., construction and protection of—1209—G. Johnson.
 Steam engines—1195—A. Wylie and J. McF. Gray.
 Steam engines, marine condensing—1243—T. Wood.
 Tombstones, application of devices to—1130—A. Grainger and C. M.
 Girdler.
 Topograph—84—A. F. Lendy.
 Turkish towelling—1281—J. Gorton.
 Window sashes and frames—1273—J. Casey.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at 8 o'clock.

JUNE 7TH.—*No Meeting.*—Owing to the Whitsun holidays and the consequent absence of many specially interested in the subject, it has been thought best to postpone the reading of Mr. Hawes's paper, "On the Policy of an Amalgamation of the Railways of the United Kingdom under Government Management," till next session.

CONVERSAZIONE.

The Council have arranged for a *Conversazione* on Wednesday, the 14th June, at the South Kensington Museum, cards for which will shortly be issued.

ANNUAL CONFERENCE.

The Fourteenth Annual Conference between the Council and the Representatives of the Institutions in Union and Local Boards will be held on Wednesday, the 14th June, at Twelve o'clock, noon. WILLIAM HAWES, Esq., Chairman of the Council, will preside.

Secretaries of Institutions and Local Boards are requested to send, as soon as possible, the names of the Representatives appointed to attend the Conference.

The Council will lay before the Conference the Secretary's Report of the Proceedings of the Union for the past year, and the Results of the Examinations, as well as the Programme of Examinations, Elementary and Final, for 1866.

The following subjects are suggested for discussion:—

1. The establishment of organising teachers among the Institutes, on the plan adopted in the East Lancashire Union.
2. Is any modification of the present scheme of Elementary Examinations, by rendering it more adapted to the capacities of class pupils in Mechanics' Institutes, desirable?
3. The advantages of local prizes to successful candidates, at the Society of Arts' Examinations, as a stimulus to local competition.

4. Whether any special inducements can be held out to lead soldiers to avail themselves of the Society's Examinations?

5. The propriety of adding to the Society's Examinations the subject of "Practical Gardening," in accordance with a proposal made to the Council by the Royal Horticultural Society, who have expressed their willingness to offer prizes in this subject.

6. How can Institutions promote the Physical Education of their members?

7. How may Popular Readings and Entertainments be made to promote the efficiency of Institution Classes?

8. The advantage of Garden Allotments, as a feature of the Institute, with the view of healthful recreation for the members.

9. Should Institutes promote the establishment of Horticultural Shows, Building Societies, Penny Savings Banks, and similar movements towards the social amelioration of the people?

10. The advantages and disadvantages of subscriptions to Institutes being paid by weekly or other small amounts.

Notice should be given to the Secretary of the Society of Arts of any other subjects which Institutions or Local Boards may desire their Representatives to introduce to the notice of the Conference.

Representatives of Institutions and Local Boards attending the Conference are invited to the Society's *Conversazione*, at the South Kensington Museum, on the evening of the same day (14th June), and will receive cards on application at the Society's House, on the day of the Conference.

Secretaries of Institutions are requested to forward, *at once*, by book post, copies of the last Annual Reports of the Institutions.

INTERNATIONAL EXHIBITION OF 1862.—JURY REPORTS.

The Council beg leave to announce that there are a small number of copies remaining of these Reports, which may now be had on application at the Society's House, price £1 5s. in cloth, or £1 11s. 6d. bound in morocco.

FINAL EXAMINATION, 1865. PRIZES AND CERTIFICATES AWARDED TO CANDIDATES.

PRIZES.

HIS ROYAL HIGHNESS THE PRINCE CONSORT'S PRIZE OF TWENTY-FIVE GUINEAS TO
200—Thomas Healey, 25, of the Burnley Mechanics' Institution, book-keeper, who has obtained
the following First-class Certificates :—

1862.	Arithmetic—First-class Certificate.	
"	English History—First-class Certificate, with Second Prize.	
1863.	Book-keeping—First-class Certificate.	
1864.	Algebra—First-class Certificate, with First Prize.	
"	Mensuration—First-class Certificate, with Second Prize.	
"	Chemistry—First-class Certificate, with Second Prize.	
1865.	Music—First-class Certificate, with First Prize.	
"	Animal Physiology—First-class Certificate, with First Prize.	

Arithmetic ...	1st Prize	£5	To No. 334—James Birch Brown, 20, Gilford Young Men's Mutual Improvement Society, clerk
	2nd Prize	3	" 659—Thomas Hodgson, 16, City of London College, clerk
Book-keeping	1st Prize	5	" 920—John Thomas Wright, 20, Werneth Mechanics' Institute, clerk
	2nd Prize	3	" 1088—John Deane, 27, Salford Working Men's College, cashier
Algebra	1st Prize	5	" 227—William Wilkins, 18, Chatham and Rochester, Strood and Brompton Mechanics' Institute, clerk
	2nd Prize	3	" 697—James Rigby Smith, 24, City of London College, clerk
Geometry ...	1st Prize	5	" 383—James Wade, 28, Glasgow Athenaeum, cashier
	No Second Prize awarded.*
Mensuration	No Prizes awarded.†
Trigonometry	No Prizes awarded.†
Conic Sections	No Prizes awarded.†
Navigation & Nautical Astronomy ...	1st Prize	5	" 307—Henry George White, 23, Devonport Mechanics' Institute, shipwright
	2nd Prize	3	" 706—William Vaughan, 24, City of London College, clerk
Astronomy	No Prizes awarded.†
Principles of Mechanics ...	1st Prize	5	" 706—William Vaughan, 24, City of London College, clerk
	No Second Prize awarded.*
Practical Mechanics	No Prizes awarded.†
Electricity & Magnetism ..	1st Prize	5	" 614—Herbert Burgess Brain, 24, City of London College, clerk
	2nd Prize	3	" 344—William Arnet, 22, Popular Evening Classes, Andersonian University, Glasgow, manufacturing chemist
	1st Prize	5	" 342—William Barr, 20, Popular Evening Classes, Andersonian University, Glasgow, chemist
Light & Heat.	2nd Prize	3	" 755—James Sutherland Simon, 28, London Mechanics' Institute, clerk
	1st Prize	5	" 340—Edmund George Tosh, 18, Popular Evening Classes, Andersonian University, Glasgow, chemist.
Chemistry ...	2nd Prize	3	" 166—George Gillford, 18, Bristol Trade School, laboratory assistant
Mining and Metallurgy	No Prizes awarded.†
	1st Prize	5	" 1104—George Stanton, 24, Maidenhead Mechanics' Institute, gardener; together with the Royal Horticultural Society's Prize of £5
Botany	No Second Prize awarded.*
Agriculture	No Papers were worked in this subject.
Animal Physiology (in relation to health)	1st Prize	5	" 200—Thomas Hanley, 25, Burnley Mechanics' Institution, book-keeper
	2nd Prize	3	" 76—Charles Taylor, 16, Banbury Mechanics' Institute, clerk
	3rd Prize†	2	" 1237—David Griffiths, 26, Leeds Mechanics' Institute, book-keeper
	No additional Prizes of Books awarded.‡
Domestic Economy	1st Prize	5	" 1336—Joseph Harrison, 23, Bradford Mechanics' Institute, clerk
	2nd Prize	3	" 662—John Hughes, 21, City of London College, chemist's assistant

* No other Candidate obtained a First-class Certificate in these subjects.

† No Candidate obtained a First-class Certificate in these subjects.

‡ Additional by gift of Harry Chester, Esq.

§ No Book Prize in this subject was awarded, the only other Candidate who obtained a First-class Certificate being disqualified from receiving Prizes.

Political and Social Economy	<i>No Prizes awarded.†</i>	
Geography...	1st Prize	5	281—Charles Jones Ellis, 25, Devonport Mechanics' Institution, shipwright in Her Majesty's Dockyard
	2nd Prize	3	608—Henry Gurson Batley, 20, City of London College, clerk
	1st Prize	5	699—William Spiers, 18, City of London College, clerk
	2nd Prize	3	676—Hugh Morgan, 18, City of London College, banker's clerk
	3rd Prize¶	2	632—Thomas William Davies, 22, City of London College, accountant
English History	Three Prizes of Books, to the value of £1 each¶	1	383—James Wade, 28, Glasgow Athenæum, cashier
		1	666—John Kennedy, 20, City of London College, clerk in Her Majesty's Customs
		1	774—Thomas Davies, 21, St. Stephen's (Westminster) Evening School, Civil Service
	1st Prize	5	686—Henry Thomas Pollard, 17, City of London College, clerk
	2nd Prize	3	383—James Wade, 28, Glasgow Athenæum, cashier
	3rd Prize¶	2	75—Arthur William Jakeman, 16, Banbury Mechanics' Institute, clerk
English Literature.....	One Prize of Books to the value of £1¶	1	1219—William Todd, 18, Leeds Mechanics' Institute, woollen manufacturer
		1	1336—Joseph Harrison, 23, Bradford Mechanics' Institution, clerk
Logic & Mental Science...	1st Prize	5	716—Thomas Wilson, 23, Royal Polytechnic Local Board, clerk
	2nd Prize	3	1059—Edwin Law, 19, Salford Working Men's College, clerk
Latin and Roman History...	1st Prize	5	688—Andrew Muirhead, 48, Leicester Church of England Institute, staff sergeant
	2nd Prize	3	371—James Binnie, 20, Glasgow Athenæum, clerk
French.....	1st Prize	5	9—James Tait, 22, Aberdeen Mechanics' Institution, clerk
	2nd Prize	3	618—James Woodward Burke, 17, City of London College, commercial clerk
German	2nd Prize	3	549—Edward Konrad Reinold, Hull Young People's Christian and Literary Institute, engineer (apprentice)
	1st Prize	5	628—Samuel Court, 37, City of London College—in the Money Order Office, Lombard-street
Italian	2nd Prize	3	719—Annie Letitia MacKechnie, 29, Royal Polytechnic Institution
	1st Prize	5	626—James Clayton, 31, City of London College, sorter, General Post-office
Spanish	2nd Prize	3	687—William Price, 29, City of London College, clerk.
Free-hand Drawing	<i>No Prizes awarded.**</i>
Geometrical Drawing ...	1st Prize	5	140—Edwin Alexander Merry, 20, Bristol Trade School, architect's clerk
	2nd Prize	3	1096—John Sargeant, 20, Slough Mechanics' Institution, carpenter
	1st Prize	5	200—Thomas Healey, 25, Burnley Mechanics' Institution, book-keeper
Theory of Music	2nd Prize	3	355—John Hunter Connell, 19, Popular Evening Classes, Andersonian University, Glasgow, clerk.

† No Candidate obtained a First-class Certificate in this subject.

¶ Additional, by gift of Sir C. Wentworth Dilke, Bart.

The other Book Prizes in this subject were not awarded; the other Candidates obtaining First-class Certificates being disqualified from receiving Prizes.

** The only Candidate who obtained a First-class Certificate in this subject was disqualified from receiving Prizes.

CERTIFICATES.

The following is an Alphabetical List of the Candidates who have obtained Certificates:—

(1st) after a subject signifies a First-class Certificate.
(2d) " " Second-class "
(3d) " " Third-class "

(The occupations stated are either present or proposed.)

- No. 602—Abell, Edward Garland, 16, City of London Coll., clerk—French (3d)
739—Absolon, William H. de Mansfield, 23, Royal Polytech. Inst., clerk—Bkpg. (1st)
415—Adam, John, 19, Glasgow M.I., mason—Arith. (2d); Bkpg. (2d)
1175—Adams, Frederick J., 19, West Bromwich Young Men's Christ. Inst., chemist and druggist—Chem. (3d)

- 1362—Adcock, John H., 17, Hackney Working Men's Institute, teacher—Arith. (1st); Alg. (3d)
731—Albin, Maria Juliette, 28, Royal Polytech. Inst.—Italian (3d)
83—Alderson, Emily, 27, Birmingham and Midland Inst., daily governess—German (3d); French (2d)
*84—Alderson, Louisa, 29, Birmingham and Midland Inst., daily governess—Eng. Lit. (3d)
21—Alexander, Henry, 23, Aberdeen M.I., engineer—Princ. Mech. (3d)
333—Alexander, Samuel, 18, Gilford Young Men's Mut. Imp. Soc., clerk—Arith. (2d)
*82—Alexander, William, 19, People's Reading Rooms, Belfast, teacher—Arith. (1st); English Hist. (2d); Geom. (2d); Alg. (3d)
1106—Allcott, James H., 21, Southampton Athenæum, officer of customs—Arith. (1st)
826—Alley, Peter Bradshaw, junr., 16, Manchester M.I., architect—Free-hd. Dwg. (2d)

- *491—Anderson, James, 27, Glasgow M.I., clerk—Mens. (2d)
 256—Anderson, Miss, Stewart, 17, Glasgow Inst.—Bkpg. (3d)
 85—Anderton, John G., 21, Birmingham and Midland Inst., optician—Light and Heat (2d)
 159—Anningson, Joseph W., 18, Burnley M.I., druggist Anim. Phys. (2d)
 362—Arteckle, Hugh Wight, 18, Pop. Ev. Classes, Anders. Univ., Glasgow, student—Chemistry (2d)
 592—Arteckle, John, 19, Paisley Artizans' Inst., clerk (writer's)—Arith. (3d)
 344—Arnot, William, 22, Pop. Ev. Classes, Anders. Univ., Glasgow—Elect. and Mag. (1st), with 2d prize; Chem. (2d)
 23—Ashby, John Thomas, 18, Farnham Young Men's Inst., teacher—Arith. (2d); Eng. Lit. (1st); Free Hand Draw. (1st)
 875—Ashmore, Isaac, 18, St. Thomas' Young Men's Christ. Inst., pupil teacher—Arith. (3d); Eng. Hist. (3d)
 529—Ashton, Thomas, 23, Henshaw-street (Oldham) Mut. Imp. Soc., minder—Arith. (3d)
 330—Ashton, William, 24, Henshaw-street (Oldham) Mut. Imp. Soc., mechanic—Dom. Econ. (2d)
 591—Ashworth, Henry, 20, Mosley M.I.—Bkpg. (1st)
 797—Aspinall, George, 20, Manchester M.I., warehouseman—Bkpg. (1st)
 796—Aspinall, John, 18, Manchester M.I., clerk—Bkpg. (1st)
 1291—Aston, William, 31, Redditch Lit. and Sci. Inst., needle finisher—Anim. Phys. (3d)
 86—Atkins, Alfred Hodgetts, 18, Birmingham and Midland Inst., pupil teacher—Chem. (2d)
 262—Atkinson, John Ainscough, 22, Crewe M.I., post messenger—Arith. (1st)
 1032—Atkinson, John H., 19, Salford Working Men's Coll., merchant's clerk—German (2d)
 209—Atkinson, Robert, 19, Burnley Ch. of Eng. Lit. Inst., roller coverer—Arith. (3d); Chem. (3d)
 36—Attfield, Ernest, 17, Farnham Young Men's Inst., bank clerk—Bkpg. (3d)
 325—Austin, Frederick, 17, Faversham Inst., clerk—Eng. Hist. (2d)
 274—Bailey, George, 23, Devonport M.I., shipwright—Eng. Hist. (3d)
 182—Bailey, John, 18, Nelson M.I. weaver—Anim. Phys. (3d)
 942—Bailey, John Hyde, 17, Oldham Lyceum, bank clerk—Bkpg. (1st)
 415—Baird, John, 22, Glasgow Inst., warehouseman—Free-hd. Dwg. (2d)
 1369—Baker, Alfred B., 17, Lambeth Local Board, clerk—Arith. (2d)
 753—Ballard, Elizabeth Ruth, 23, London M.I.—Eng. Lit. (3d)
 28—Bank, George, 26, Accrington M.I., stoker—Arith. (3d)
 1192—Banks, Joseph, 17, Wolverhampton W. Men's Coll., clerk—Arith. (1st)
 605—Banister, Arthur, 19, City of London Coll., clerk—Bkpg. (1st)
 178—Bannister, James, 26, Nelson M.I., warehouseman—Arith. (2d)
 178—Barker, Charlotte S. M., 17, Bristol Ath.—Eng. Hist. (3d); French (2d)
 606—Barker, Frank Cowlin, 19, City of London Coll., merchant's clerk—German (1st)
 183—Barker, John, 22, Nelson M.I., weaver—Chem. (2d); Anim. Phys. (3d)
 868—Barker, Miles, 22, Swinton M.I., colliery clerk—Arith. (2d); Mens. (3d)
 1034—Barker, William T., 17, Salford W. M. Coll., warehouseman—Arith. (3d)
 165—Barkla, William, 23, Bristol Ath., book-keeper—Arith. (3d); Bkpg. (2d)
 607—Barlow, William, 32, City of London Coll., merchant's clerk—Bkpg. (2d)
 237—Barlow, William Crosby, 28, Christchurch W.M. Inst., minister (teacher)—Botany (3d)
 561—Barnes, Benjamin Thomas, 17, Ipswich W.M.C. clerk—Bkpg. (2d)
 130—Barnes, Robert, 18, Bolton M.I., millwright—Mech. Dwg. (3d)
 342—Barr, William, 20, Pop. Evg. Classes, Anders. Univ., Glasgow, chemist—Light and Heat (2d) with 1st prize
 47—Barr, William H., 20, Bacup M.I., druggist's assistant—Chem. (2d); Anim. Phys. (3d)
 1227—Barrett, Arthur G., 18, Leeds M.I., clerk—Chem. (3d)
 931—Barrow, Henry Mills, 22, Oldham Lyceum, attorney's clerk—Geom. Dwg. (3d)
 583—Barron, Thomas H., 19, Leeds Y.M.C. Assn. clerk—Arith. (2d)
 1296—Bartleet, Charles, 16, Redditch Lit. and Sci. Inst., warehouseman—Bkpg. (3d)
 87—Barwell, Sarah Maria, 16, Birm. and Midl. Inst.—French (3d)
 843—Batchelor, Charles, 19, Manchester M.I., engineer—Geom. Dwg. (1st)
 805—Bateman, Thomas, 21, Manchester M.I., clerk—Bkpg. (1st)
 827—Bates, Arthur, 27, Manchester M.I., clerk—Bkpg. (1st); French (2d); Geom. Dwg. (3d)
 497—Bates, John Dalton, 18, Halifax M.I., woolsorter—Bkpg. (2d)
 1138—Batham, David, 17, Woodside Iron Works Ltd. Soc., messenger—Arith. (3d)
 608—Batley, Henry Gurnson, 20, City of London Coll., clerk—Geog. (1st) with 2d prize.
 88—Baylis, Thomas, 18, Birmingham and Midland Inst., leather dealer—Arith. (1st)
 564—Beaumont, Barrington Gooding, 19, Ipswich Working Men's Coll., clerk—Bkpg. (1st)
 980—Beedham, John, 23, Oldham Science School, surveyor's clerk—Geom. Dwg. (1st)
 1108—Beer, Thomas, 25, Southampton Athenaeum, clerk—Music (3d)
 609—Begent, George T., 19, City of London Coll., clerk—Bkpg. (2d); Arith. (3d); Geog. (3d)
 736—Belfrage, David McL., 30, Royal Polytech. Inst., clerk—Bkpg. (2d)
 31—Bell Joseph, 17, Acomb Lit. Inst., clerk—Arith. (3d)
 1165—Bennett, James, 27, Kinver Young Men's Assn., carpenter—Geom. Dwg. (3d)
 1142—Bennett, John, 23, Kinver Inst., registrar of births and deaths—Arith. (2d); Latin, &c. (3d)
 154—Bennett, Philip, 16, Bristol Trade School, bookbinder—Geom. Dwg. (1st)
 890—Berry, Joseph, 33, Mosley M.I., warehouseman—Bkpg. (2d)
 89—Best, Howard, 17, Birmingham and Midland Ld. die sinker—Elect. and Magn. (3d)
 80—Best, James, 18, People's Reading Rooms, Belfast, assistant teacher—Arith. (3d); Mens. (3d)

PARIS EXHIBITION OF 1867.

The following is a list of the Commissioners appointed by Her Majesty to advise her upon the best mode of exhibiting the products of industry and the fine arts of the United Kingdom, the British Colonies and Dependencies to be procured and sent to this Exhibition, viz. :—
The Prince of Wales, K.G.; Earl Granville, K.G.

President of the Chamber of Commerce of Belfast for the time being; John M'Ewen, Esq., Chairman of the Chamber of Commerce of Glasgow, or the Chairman of the Chamber of Commerce of Glasgow for the time being; John Francis Maguire, Esq., M.P.; Philip W. S. Miles, Esq., President of the Chamber of Commerce of Bristol, or the President of the Chamber of Commerce of Bristol for the time being; John Moreton, Esq., Chairman of the Chamber of Commerce of Wolverhampton, or the Chairman of the Chamber of Commerce of Wolverhampton for the time being; Robert Napier, Esq., President of the Institute of Mechanical Engineers, or the President of the Institute of Mechanical Engineers for the time being; Philip Henry Rathbone, Esq., President of the Chamber of Commerce of Liverpool, or the President of the Chamber of Commerce of Liverpool for the time being; Richard Redgrave, Esq., R.A., H.M.'s Surveyor of Pictures; Henry W. Ripley, Esq., Chairman of the Chamber of Commerce of Bradford, or the Chairman of the Chamber of Commerce of Bradford for the time being; Richard Russell, Esq., President of the Chamber of Commerce of Limerick, or the President of the Chamber of Commerce of Limerick for the time being; Major-General Edward Sabine, President of the Royal Society, or the President of the Royal Society for the time being; Wm. Scholefield, Esq., President of the Chamber of Commerce of Birmingham, or the President of the Chamber of Commerce of Birmingham for the time being; John Sharp, Esq., President of the Chamber of Commerce of Dundee, or the President of the Chamber of Commerce of Dundee for the time being; Frederick Tayler, Esq., President of the Society of Painters in Water Colours, or the President of the Society of Painters in Water Colours for the time being; Henry Thring, Esq.; Henry Hussey Vivian, Esq.; and Henry Cole, Esq., C.B., Secretary.

The Commissioners held their first meeting in the Lecture Theatre of the South Kensington Museum on Saturday, the 27th May. His Royal Highness the Prince of Wales presided. The Commissioners decided to divide themselves into twelve or more sub-committees, to take charge of the various groups into which the exhibition will be classified.

Fine Arts.

THE EXHIBITION OF PORTRAIT MINIATURES, consisting of between three and four thousand specimens of all the great masters, from the time of Holbein, will be opened to the public at the South Kensington Museum to-morrow (Saturday).

Manufactures.

PRESERVATION OF FLOWERS WITH THEIR NATURAL COLOURS.—Dried flowers, in their natural colours, have for some time past appeared for sale in the shops; the mode in which the operation is effected is this:—A vessel, with a moveable cover, is provided, and having removed the cover from it, a piece of metallic gauze of moderate fineness is fixed over it, and the cover replaced. A quantity of sand is then taken sufficient to fill the vessel, and passed through a sieve into an iron pot, where it is heated, with the addition of a small quantity of stearine, carefully stirred, so as to thoroughly mix the ingredients. The quantity of stearine to be added is at the rate of half a pound to one hundred pounds of sand. Care must be taken not to add too much, as it would sink to the bottom and injure the flowers. The vessel with its cover on, and the gauze beneath it, is then turned upside down, and the bottom being removed, the flowers to be operated upon are carefully placed on the gauze and the sand gently poured in, so as to cover the flowers entirely, the

leaves being thus prevented from touching each other. The vessel is then put in a hot place, such for instance as the top of a baker's oven, where it is left for forty-eight hours. The flowers thus become dried, and they retain their natural colours. The vessel still remaining bottom upwards, the lid is taken off, and the sand runs away through the gauze, leaving the flowers uninjured.

Notes.

PARIS EXHIBITION OF 1867.—The amount of the guarantee asked for, namely, eight millions of francs, has been subscribed, the large companies, some bankers, and many rich manufacturers having taken up the matter very energetically. The sum named above was that first of the maximum, but the amount was not limited, the subscription will therefore be left open for some time. The appointment of the remaining nineteen members of the commission, who will be the representatives of the guarantors, is to take place by the end of the present month.

PUBLIC WORKS IN FRANCE.—The Government has opened a credit of 360,000,000 francs, to be raised by the sale of crown lands during the coming six years, and devoted in the following manner:—For roads and bridges, 95 millions; rivers, 63 millions; canals, 32 millions; maritime ports, 135 millions; hydraulic works and agricultural improvements, 35 millions. Amongst the great works in contemplation are two canals, one to make direct communication between Paris and Pontoise, passing through the valley of Montmorency; starting from the Oise, near Saint Ouen l'Aumône, it will traverse Herbigny, Montigny, Franconville, Epinay, Saint Denis, and Aubervilliers, where it will cross the canal of Saint Denis; the other is to be an embankment of the former, commencing at Herbelay, and ending at Conflans Sainte Honorine.

THE BOMBAY INTERNATIONAL EXHIBITION is now being carried out (says the *Bombay Gazette*) on a system of guarantees, and the Joint-Stock Company is to be wound up. Mr. T. C. Hayllar has been appointed managing director in Bombay.

CRYSTAL PALACE AT OPORTO.—The Portuguese journal state that an edifice, entirely composed of glass and iron in the style of the Crystal Palace at Sydenham, is about to be erected at Oporto, on the hill of Torre di Mar, just outside the town. It is intended for the exhibition of all the productions of Portuguese industry, as well as the natural products of the country.

Correspondence.

ON THE WEAR AND TEAR OF STEAM BOILERS.

SIR,—While reminding Mr. D. K. Clark that I need not state that an edifice, entirely composed of glass and iron in the style of the Crystal Palace at Sydenham, is about to be erected at Oporto, on the hill of Torre di Mar, just outside the town. It is intended for the exhibition of all the productions of Portuguese industry, as well as the natural products of the country.

1. That my explanations, such as they are, of the mechanical effects of heat in the wear and tear of boiler-boilers, I will, in the same way as with regard to painting and furrowing, now prove, in an easily accessible form.

2. That everything which he adduces as explanatory of these effects was published by others years before the issue of his work on the "Recent Practice in the Locomotive Engine."

3. That such publication was perfectly well known to Mr. D. K. Clark at the time (1860) he published his book;

4. That the information I have derived from other people has been fully acknowledged by myself.

I will now proceed to prove these small matters by *verisim* references to the original documents:—

MR. D. K. CLARK'S THEORY (*in extenso*) OF THE MECHANICAL EFFECTS OF THE HEAT ON THE WEAR AND TEAR OF BOILERS.

Your Correspondent's Explanation will be found at pp. 391-2 of the *Journal* for April 28th.)

At page 17 of "Recent Practice in the Locomotive Engine," published in 1860, Mr. D. K. Clark says:—

"Copper expands by heat half as much again as iron, and taking the mean temperature of the copper of the fire-box at twice as much as that of the shell, an assumption which, we suppose, is something much below the fact, the vertical expansion of the fire-box would be, upon the whole, three times as much as that of the shell, and the difference of expansion would be twice that of the iron, or at the rate of 1 in 500. On a fire-box 5 ft. 3 in. high, the difference of expansion would, at this rate, amount to one-eighth of an inch. That is to say, the upper stay bolts would be deflected one-eighth of an inch from their normal position when under the power of high-pressure steam. On a length of stay bolt of 3 in., a deflection of one-eighth of an inch is immoderate; and, considering the alternate expansion and contraction, bending and relaxing, attendant upon getting up steam and letting it down, it is reasonable to conclude that the same cause of degradation is at work with the stay bolts as that already suggested for boiler plates at the rivet joints—the alternation of strain, tension, and relaxation, which loosens the texture and ultimately overcomes the cohesion of the material so treated, incurring parallel fracture and accelerated corrosion. On this argument the failure of stay bolts should—as in fact it is—be localised at or near their junctions with the plates, which are the points of maximum strain, similarly to the localisation of furrows near rivet joints. Occasionally, entire rows of rivets are found to be snapped across close to the plate, independently of corrosive action, suggesting a cause of failure precisely the same as that which breaks axles, an alternating lateral strain and vibration beyond the limits of enduring elasticity."

"The reasons above advanced afford an explanation of the fact that fire-boxes with narrow water spaces are more subject to leakage than those with wider spaces, the stays being shorter and less flexible in the former case, and likelier to fail. For the same reasons, stay bolts of smaller diameter, sufficiently strong, are preferable to others of larger diameter. They are more elastic, and yield to unequal expansion more readily than thicker stays, and are, therefore, likely to be more durable."

"The oblique strain to be resisted is similar in character to that which tells upon weak wrought iron-wheel spokes under excessive shrinkage of tyres converting them into serpentine and wye forms, as the duration of wheel spokes, under such circumstances, is increased by expanding them towards their junction with the nave and with the rim, and rounding them off; so that if stay-bolts are improved by turning off the thread in the middle part, now sometimes done, probably the application of the principle might be advantageously extended; and our belief is that a superior iron stay-bolt may be made more resilient of the forms (see figure) in which a *gin* screw is turned down to *gin*, or *fin*, diameter at the middle."

When I first read the above explanations, coupled with the proposed remedy, I was greatly struck with them. I did not then know that Mr. D. K. Clark has not the slightest claim to originality in the whole matter. Both the disease and its remedy have been described years before the publication of Mr. Clark's work.

In "Colburn's Railway Advocate" (New York), No. 25, of the 27th of October, 1855, page 2, we read, under the heading of "Breakage of Boiler Stay-bolts:—"

"An attentive friend, Mr. George Richards, at the repair shop of the Boston and Providence-road, at Roxbury, Mass., writes us in regard to the above subject, and advances the explanation that the difference in the expansion of the inside and outside fire box shells is one, if not the only, cause of the breaking of stay-bolts. His letter, which we copy below, deserves attention, as the facts which he presents tend to establish the correctness of his views."

"A boiler has been recently examined at the Boston and

Providence railroad shop, and many of the screw stay-bolts were found broken close to the outside sheet. This engine has been in almost constant use for upwards of eight years. The bolts were not wasted away at all, but broken short off. Other boilers have been examined previous to this, and bolts were found broken in the same manner; the broken bolts were invariably in the upper rows. His evidence goes to prove that the cause of the breaking of the bolts is the different expansion of inside and outside sheets of fire-box, as the upper bolts are subject to more of that expansion. The screw also helps to break the bolts. The engine spoken of has been fired up and cooled off at least two thousand times; consequently, the stay-bolts have been strained that same number of times, besides being subject to the usual boiler pressure. Mr. Griggs has been supplying the places of the broken bolts with new ones, which he has turned down a little below the thread, between the sheets, which will allow them to spring, as the inside fire box expands upwards more than the inside. If the different expansion of the sheets is the cause of the bolts breaking, I think that they will not break if used long enough."

It seems to me that anybody who chooses to compare Mr. D. K. Clark's account with mine must feel as astounded as myself at his statement, that, "my explanation of the destructive action of the unequal expansion of the fire-box of locomotives, and the shell, upon the stay bolts, in straining them laterally beyond the limits of elasticity, and thus permanently weakening them, was published at the same time [*'Recent Practice,'* pp. 16, 17], and, I think, anticipates *all* that Mr. Paget has just written on the same subject." This astonishment would of course arise even on the supposition of the existence of originality of conception on his part,—in fact, notwithstanding the extraordinary coincidence that the diagnosis of the disease and its remedy, both put forward as his own by Mr. Clark, were both published years previous. It might, perhaps, be said that he could not be expected to know what had been published in a New York periodical. But what will be really said when I mention that Mr. Zerah Colburn, the then editor of the New York "Railroad Advocate," distinctly affirms to me that he sent that very number, and other numbers, to Mr. D. K. Clark? Besides, the columns of Mr. Colburn's periodicals, containing, as they do, letters from Mr. D. K. Clark, bear public testimony to a correspondence of that date between these two gentlemen. Again, that portion of "Recent Practice in the Locomotive Engine," written by Mr. Colburn, includes the same statements.

It is, however, just possible that, by some chance, or rather miracle—and miracles are events beyond the doctrine of chances—Mr. Clark, without having seen Mr. Griggs' remarks, published five years previous, may have evolved the whole from his own "internal consciousness."

18, Adam-street, Adelphi, 27th May.

F. A. PAGET.

ANCHORS AND CHAIN CABLES.—SIR,—In your report of the discussion on Mr. Gladstone's paper, you have made me responsible for the production of steel anchors and cables at £25 per ton, whereas I stated that *cast steel* anchors could be manufactured at from £55 to £75, and *puddle steel* cables at £25 per ton, the latter of the same size, but of nearly double the strength, as the iron cables represented in Mr. Gladstone's paper as costing £15. Please correct this, and oblige,—Yours, &c., T. A. ROCHUSSEN.

Gun cotton, preparation of—1102—F. A. Abel.
Gun barrels—1341—W. Deakin.
Hathlocks, machinery for shaping—258—W. H. Higgins.
Hinges—1335—William Clark.
Hose, manufacture of—1309—T. J. Mayall.
Hydrocarbons, apparatus for distilling—1361—G. Walton.
Jacquard machines—1298—J. Melvin.
Jute, preparation of—1262—J. McGlashan.
Lamps—1268—W. C. Cropp.
Land, machinery for cultivating—1134—J. Howard and E. T. Bousfield.
Leather, tanning—1126—E. S. Beaux and E. Pennifox.

- Lithographic impressions, producing—1325—G. and G. W. Stinson.
Locks—1201—W. Clark.
Locks—844—R. Nabbs.
Locomotive, wheels for—1114—W. Day.
Luggage, balance for weighing—115—A. C. Herrmann.
Moulds for casting pipes—1206—D. Y. Stewart.
Oil, vessels for containing—1359—S. Svendsen.
Pens, apparatus for shelling—1244—E. G. Smith.
Pencil, manufacture of—1339—J. F. Cooke.
Pipes, apparatus for cutting metal—1311—G. Mountford and E. Ploughs—1246—J. Stalkart.
Worroll.

- Portraits, materials for producing—1184—A. Grainger & C. Mitchell.
Printing machinery—1026—D. Payne.
Pulleys, spring apparatus for—1343—G. Elliott and B. Cozen.
Railway trains, communication between passengers and guard of—129—J. H. Johnson.
Railways, apparatus for laying single line—1321—R. Winder.
Railways, effecting traction on—1322—R. E. Donovan & D. O'Brien.
Railway trains, communication by signals between different parts of—1363—M. Defries.
Rivets, machinery for making—1367—R. Leddicost.
Roads, constructing—1260—J. Mitchell.
Safety-valve—1305—J. H. Johnson.
Safety lamps—1274—J. H. Johnson.
Sewing machines—1166—J. and W. Fairweather.
Sewing machines—1331—J. K. Caird.
Ships, &c., construction of—1083—W. Bodder.
Signals, machinery for transmitting—1258—A. H. Branden.
Tubs, manufacture of—1337—F. Keanes.
Spirits, apparatus for measuring—1272—J. H. Johnson.
Soles, clogs and patten—1351—W. Brown.
Starch, treating rice for manufacture of—1319—H. Ramsford.
Stays, fasteners for—1284—G. Hartley.
Steam engines—1264—W. E. Newton.
Tubes, apparatus for fixing—1282—R. H. Tweddell.
Type, machinery for distributing—1262—A. Mackie, H. Garvie, and J. Salmon.
Type, machine for dressing printer's—1277—P. Welsh.
Umbrellas, metal ribs for—1302—R. Hadfield and J. Shipman.
Vessels, propellers for—1139—R. H. Dart.
Vessels, composition for coating—1278—J. C. C. Halkett.
Vinegar, brewing—1263—S. Bennett.
Water, process for purifying—1242—C. G. Lenk.
Wheels, railway—1158—J. T. Buckhill.
Wires, apparatus for tapering—1363—C. O. Crosby.

INVENTION WITH COMPLETE SPECIFICATION FILED.

- Machines, rotary magnets electric—1368—T. Fauchoux.
Oils, lamps for burning mineral—1410—P. A. le C. de Fontaine-Moreau.
China, clays for the manufacture of—1414—A. Hett.

Announcements by the Council.

CONVERSAZIONE.

The Council have arranged for a Conversazione on Wednesday, the 14th June, at the South Kensington Museum, cards for which have been issued.

DINNER.

Some of the Vice-Presidents and Council propose to dine together on Monday, the 26th inst. Any Members of the Society desiring to join the party are requested to communicate with the Secretary forthwith.

Tickets (one guinea each) will be ready for delivery at the Society's house on and after Friday next, the 16th inst., but application should be made without delay, in order to facilitate the arrangements.

ANNUAL CONFERENCE.

The Fourteenth Annual Conference between the Council and the Representatives of the Institutions in Union and Local Boards will be held on Wednesday next, the 14th June, at Twelve o'clock, noon. WILLIAM HAWES, Esq., Chairman of the Council, will preside.

Secretaries of Institutions and Local Boards are requested to send, as soon as possible, the names of the Representatives appointed to attend the Conference.

The Council will lay before the Conference the Secretary's Report of the Proceedings of the Union for the past year, and the Results of the Examinations, as well as the Programme of Examinations, Elementary and Final, for 1866.

The following subjects are suggested for discussion:—

1. The establishment of organising teachers among the Institutes, on the plan adopted in the East Lancashire Union.
2. Is any modification of the present scheme of Elementary Examinations, by rendering it more adapted to the capacities of class pupils in Mechanics' Institutes, desirable?
3. The advantages of local prizes to successful candi-

dates, at the Society of Arts' Examinations, as a stimulus to local competition.

4. Whether any special inducements can be held out to lead soldiers to avail themselves of the Society's Examinations? [See the subjoined correspondence with His Royal Highness the Field-Marshal Commanding-in-Chief.]

5. The propriety of adding to the Society's Examinations the subject of "Practical Gardening," in accordance with a proposal made to the Council by the Royal Horticultural Society, who have expressed their willingness to offer prizes in this subject.

6. How can Institutions promote the Physical Education of their members?

7. How may Popular Readings and Entertainments be made to promote the efficiency of Institution Classes?

8. The advantage of Garden Allotments, as a feature of the Institute, with the view of healthful recreation for the members.

9. Should Institutes promote the establishment of Horticultural Shows, Building Societies, Penny Savings Banks, and similar movements towards the social amelioration of the people?

10. The advantages and disadvantages of subscriptions to Institutes being paid by weekly or other small amounts.

Notice should be given to the Secretary of the Society of Arts of any other subjects which Institutions or Local Boards may desire their Representatives to introduce to the notice of the Conference.

Representatives of Institutions and Local Boards attending the Conference are invited to the Society's Conversazione, at the South Kensington Museum, on the evening of the same day (14th June), and will receive cards on application at the Society's House, on the day of the Conference.

Secretaries of Institutions are requested to forward, at once, by book post, copies of the last Annual Reports of the Institutions.

EXAMINATION OF SOLDIERS.

The following documents have been forwarded to the District Unions, Local Boards, and other Institutions connected with the Society:—

The first is a letter to Field-Marshal His Royal Highness the Commander-in-Chief of the Army, from Mr. Harry Chester, inquiring whether his Royal Highness would see any objection to his announcing, at a public meeting then intended to be held at Knightsbridge,

that the examinations and classes held by the Boards and Institutions connected with this Society, were open to soldiers, their wives, and children, as well as to civilians of the working classes. It will be seen that Mr. Chester, though asking this question for his own guidance, couches it in such general terms, that the answer will serve equally for all others engaged in carrying out the scheme of examinations wherever the Society has Local Boards in any part of the kingdom. The letter was referred by the Commander-in-Chief to the Council of Military Education, for their consideration and report.

The second document is General Forster's reply to the above-mentioned letter. Before this reply was given, Mr. Chester's illness had compelled him to go abroad, under strict injunctions to abstain entirely from business, and there was no means of making known the correspondence until it was too late for the examinations of 1865.

The third document is an official memorandum recently published by command of His Royal Highness, to the same effect as General Forster's letter. The authorities of the District Unions, Local Boards, and Institutions connected with the Society will naturally see the propriety of abstaining from addressing themselves directly to the troops quartered in any place, and will in every case apply to the commanding officer, and leave it to him to determine whether and in what manner the subject shall be brought to the notice of those under his command.

I.

63, Rutland-gate, Dec. 30, 1864.

SIR,—Your Royal Highness is probably acquainted with the measures which have been taken by the Society of Arts since the Great Exhibition of 1851, to promote the education of adults of the working-classes employed in "Arts, Manufactures, and Commerce."

The Society's "Union" of Institutions for the education of adults embraces about 1,000 Institutes, Evening Schools, and "Local Boards." The latter, about 150 in number, have been called into existence expressly to carry out the scheme of educational examinations which has been established by the Society and the Institutions united thereto.

His Royal Highness the Prince Consort was pleased to take a lively interest in this scheme; and a prize of 25 guineas, which he established, "The Prince Consort's Prize," is now given annually by Her Majesty the Queen.

The scheme extends to all parts of the United Kingdom wherever a local board can be formed.

In many parts of England district unions have been formed for the better carrying out of the scheme.

A district union, called the Metropolitan Association for Promoting the Education of Adults in Union with the "Society of Arts," was formed about two years ago. Of this Association His Royal Highness the Prince of Wales (President of the Society of Arts) is patron and a life member; and Her Royal Highness the Princess of Wales is patroness, and gives an annual prize to female candidates. Earl Granville is President.

The examinations are of two kinds. There are examinations of persons not under 16 years of age, in 32 different subjects, by examiners appointed by the Society of Arts, and preparatory examinations, of persons not under 12 years of age, in elementary subjects by examiners appointed by the Association and by the Local Boards. There are also collateral examinations in religious knowledge.

I enclose, for the information of your Royal Highness, programmes of the several examinations.

The Metropolitan Association has divided the metropolitan district into sub-districts, each sub-district having or to have its "Local Board," so that the advantages of the examinations, certificates, prizes, &c., may be brought within easy reach of the working classes everywhere in and near to London.

Boards have been already formed in the neighbourhood of some of the barracks, and a Board is to be formed immediately in this neighbourhood, near to the cavalry barracks.

It has struck me that it might be a great advantage and encouragement to the soldiers there (and in other

barracks), and might tend to strengthen the excellent system of regimental and barrack instruction which your Royal Highness has already introduced, if, with the sanction in each case of the commanding officer, the soldiers, their wives, and children, not under 12 years, were invited to offer themselves for examination, and to compete for the various prizes, in common with the civilians who stand on the same social level. I do not venture, however, to say anything publicly on this subject without first understanding that it would not seem to your Royal Highness to be inexpedient that I should do so.

Finding that the "Instruction Classes" among the metropolitan police were desirous to profit by the examinations, I communicated with Sir Richard Mayne before I invited the men to present themselves.

With great respect, I submit the subject to your Royal Highness.

My wish is to be informed whether there would seem to be any objection to my stating, at the approaching public meeting for the establishment of the Local Board at Knightsbridge, that I hope the soldiers in the barracks, with their wives and children, may profit by the advantages which the Board will offer to the neighbourhood.

I have, &c.,

HARRY CHESTER.

To Field Marshal H.R.H. the Duke of Cambridge, K.G.

II.

Horse Guards, March 1, 1865.

SIR,—The Field Marshal Commanding-in-Chief having had under his consideration the proposition which you made to him on the 30th of December last, I am directed by his Royal Highness to inform you that there will be no objection to soldiers being permitted to present themselves, their wives, and children, for instruction and examination at the Educational Institutes in connection with the Society of Arts, wherever these institutions may be established in the neighbourhood of their barracks; and the distinct understanding, however, that soldiers are not in consequence to be exempted from military duty;—I have the honour to be, Sir, your obedient servant,

Harry Chester, Esq., &c.

W. F. FOREMAN.

III.

The following circular memorandum (Gen. No. 33) addressed to the army at home, has been issued:—"Miscellaneous 1 (1865).—The Field Marshal Commanding-in-Chief desires it to be notified that there will be no objection to soldiers, their wives, and families, being permitted to present themselves for instruction and examination at the Educational Institutes in connection with the Society of Arts, on the understanding that they are, on that account to be exempted from any military duty, nor, except in special cases, to be out of barracks all watch-setting or tattoo.—By command of his Royal Highness the Field Marshal Commanding-in-Chief, JAMES YORKE SCARLETT, Adj. Gen.—Horse Guards, S.W., 11th March, 1865."

NOTICE TO MEMBERS.

A working model of Mr. H. W. Reveley's direct-acting steam tilt-hammer, described in the current volume of the *Journal* (page 141) will be shown in action at the Society's House, on Friday, the 16th inst., at 11 a.m., when the attendance of members is invited.

FINAL EXAMINATIONS, 1865.

The following are corrections in the list of successful candidates:—

In No. 371.—Binnie, James, omit "French (1st) with 1st Prize," he not having worked a paper in that subject.

In No. 372.—Laughland, James, after French (1st) add "with 1st prize."

Insert No. 373.—Michaelson, Maximilian, 18, Glasgow Ath., clerk—French (1st)

Proceedings of Institutions.

HALEY-HILL WORKING MEN'S COLLEGE.—The tenth annual report, after giving a slight review of the original aims for which the college was founded, and the results which it had attained, states that during the ten years of its existence the college had fulfilled the objects of its founder. Commenced for the improvement of Haley-hill and the neighbourhood, its operations had extended to the whole of Halifax and the adjacent districts, whilst the branch at Copley had brought its advantages to the very doors of the inhabitants of that pretty village. The records of the trades and residents of the students showed that the operations of the college had been chiefly confined to the *bona-fide* working classes; and the measure of success attending the scheme was evident from the number of certificates gained in national competition from the Society of Arts, and the examinations of the Government Department of Science and Art, as well as by the valuable situations now held by many who had been under instruction in the classes. But the past had not been so satisfactory a year as several of its predecessors. The great prosperity which of late had been the portion of the working classes of Halifax and the neighbourhood had not been favourable to the success of the higher classes of the college, in consequence of so many working overtime, &c. A social economy class had been formed, both in the senior and middle divisions of the college, to which the committee attached much importance, considering it valuable in helping the students to understand many of the important questions relative to employers and workmen which were seeking solution at the present day. The young women's institute carried on its useful career in new premises. The removal of the college classes from the Haley-hill schools left those rooms at liberty, and the Principal allowed them to be appropriated to the use of the young women's classes. A second examination in scripture, domestic economy, dictation, history, geography, and arithmetic had been held, and the results, on the whole, were very satisfactory. Most of the students voluntarily took the papers, which were very creditably answered. In both of the Copley branches the work was going on well, and the comparative positions of the students of both on the class lists of the examiners showed most careful and steady working. The young men of Copley did not, however, generally take so much advantage of the opportunities for self-improvement thus offered to them as the young women. The report of the Rev. O. F. Routledge, M.A., her Majesty's inspector of schools, in reference to the Working Men's College, said—"This institution is doing its work admirably. The scholars read with great intelligence, write a neat, legible hand, and work their sums very correctly." Of the young women's institute, the inspector said—"The girls and young women have been patiently and carefully taught in all elementary knowledge, and give great promise of usefulness. The working men's college and young women's institute are doing a very great deal of good in Halifax, and are prospering very satisfactorily."

MUSICAL EDUCATION ON THE CONTINENT.

The Musical Education Committee [see page 287] have held several meetings since their appointment. One of the first steps taken by them was to request the Council to communicate with Earl Russell, Secretary of State for Foreign Affairs, with the view of obtaining, through the Foreign Office, various particulars with regard to the principal musical conservatoires on the continent, the authorities of which have, in many cases, most courteously supplied the desired information.

The Council being of opinion that abstracts of some of the documents thus received would be interesting to

the members generally, have directed their publication in the *Journal*.

There are regular colleges, or, as they are termed abroad, conservatoires, for instruction in the various branches of musical art; some entirely depending for their support upon, and under the immediate control of, the Government; and others more or less independent of State support or external authority. The largest of these institutions is the Conservatoire of Paris, maintained with the utmost liberality by the Government, and under the control of the Minister of Public Instruction. And it appears to have amply repaid both the munificence and the administration provided by the Government in the excellence of its pupils and the general effect of the extension of musical taste and knowledge throughout France as an element of social progress.

The establishment of orpheonic or choral societies throughout France, equally under the control of the Government, has also greatly tended to this beneficial result.

The Conservatoire at Leipzig has attained a great celebrity by its instruction in the deeper and more fundamental science of Harmony and Composition.

MUSICAL EDUCATION IN BAVARIA.

There is a Royal Conservatoire of Music at Munich, founded A.D. 1846. It receives a subvention from the Government of 7,000 florins—about £583. The students pay as follows:—Beginners pay 50 florins [about four guineas] per annum, from which there is no immunity. Students of the higher course pay 100 florins [eight guineas]. If natives, some are partly, or entirely, free from payment. The course of instruction is for three years. There are no boarders, and from eighty to ninety male and female pupils. The conservatoire is under the immediate control of the Minister of Public Instruction.

The Musical Institution at Würzburg is more for vocal instruction than the former. It receives a subsidy of 3,880 florins [about £323] from the State, and 847 florins [£29] from the Academy of Würzburg. The students are taught gratuitously; the number is about 150, including a great many amateurs.

Music is taught in all public schools of a higher class in Bavaria, and is obligatory in the seminaries for the education of teachers. In other schools musical instruction is optional, but in the middle schools, special music masters are appointed and salaried from the school funds, the pupils paying no fees for music.

THE CONSERVATOIRE OF LEIPZIG.

This institution is supported by various legacies, a small subscription from the King, and fees from the pupils. It receives no funds from the Government or municipality, and is therefore independent of state or civic control. It has rooms in the "Gewandhaus" at a nominal rent, but the repairs and alterations cost 6,000 thalers [£900]. It was opened at Easter, A.D. 1843, with 44 pupils.

The governing body consists of five directors, appointed by the King and Home Minister. The Minister of Public Instruction is *ex-officio* a director, and one director is a descendant of the founder, Herr Blumner. None of the directors are educated musicians, and the president is a retired lawyer.

The salary of the first director, Herr Schleinitz, is 1,000 thalers, £150. There are twenty teachers, who receive, on an average, £70 per annum. The teachers are engaged, some annually, and some only by the hour.

The following statement shows the funds from which the Academy is supported:—

	Thalers.	£ s.
1. The Blumner legacy, 20,000 thalers, at 4 per cent	800 ..	120 0
[The trustees appoint one director]		
2. From the King's privy purse ...	200 ..	30 0
[Given to six scholarships free to Saxons.]		

3. Miscellaneous legacies, 2,550 thalers, at 4 per cent.....	102 ..	15 6
4. The Helbig legacy, 1,000 thalers, at 4 per cent.....	40 ..	6 0
[This is given in premiums and musical publications as prizes]		
5. The Frege legacy, 2,000 thalers, at 4 per cent.....	80 ..	12 0
[Which provides half the charge for the education of two students.]		
6. The Mendelssohn legacy, 1,800 thalers, at 4 per cent.	60 ..	9 0
[Given as a prize to the best pupil]		
7. 143 pupils, at 80 thalers, £12 each.	11,440 ..	1,716 0
	12,722 ..	£1,908 6

The complete course of Theoretical instruction is for three years. It consists of:—

Harmony, nine classes—First year, harmony and part writing; second year, harmony and counterpoint; third year, harmony, double counterpoint, and fugue.

Form and Composition, five classes. Oral instruction and exercises; vocal and instrumental composition; analysis of classical musical works.

Playing from score; conducting, with practical exercises.

Italian language for solo singers.

There are besides lectures on various musical subjects, the æsthetics of music, &c.

Singing—solo and choral—four classes.

Instrumental playing:—1. Pianoforte; twenty classes. 2. Organ; four classes. 3. Violin and viola; solo, quartett, and orchestral; eight classes. 4. Violoncello; three classes. 5. Declamation for singers; two classes. 6. Solo playing, with accompaniment and *ensemble* playing. 7. Practice in public performance.

Instruction in the double bass and wind instruments is only given for extra fees, but it is under the control of the director. The pupils furnish their own instruments, music, and books.

Besides the above instruction, the pupils are afforded the following advantages:—They are admitted gratuitously to the rehearsals of the "Gewandhaus" concerts and to the quartette concerts, and those who are qualified play in the concerts at the gewandhaus, the oratorios, and other church performances with a large orchestra.

The musical education of France may be classified as follows:—

1.—*Superior Instruction*.—Conservatoire of Paris. Provincial Conservatoires.

2.—*Secondary Instruction*.—Lyceums and colleges.

3.—*Primary Instruction*.—Primary Normal Schools; Commercial Schools; the Orphéon Institute of Paris; courses for adults; Choral Societies and Free Orpheonic Societies.

IMPERIAL CONSERVATOIRES FOR MUSIC AND DECLAMATION IN PARIS.

The Director presides over the artistic branch; a Manager and Secretary assist him in the details of the general organisation. An Imperial Commissary overlooks the whole establishment, in connection with the Government.

More than six hundred out-door students attend the classes of the Conservatoire. The education is entirely gratuitous.

The attendance of pupils is registered by an Inspector of Classes.

Ten male students are admitted as boarders on the foundation; they are selected entirely from the best voices. The boarding establishment is under a superintendent. Two physicians are attached to the establishment. Ten female students are on the foundation, but board out; they only attend the singing classes.

The following is the List of Classes:—

- 4 Classes for Fugue, Counterpoint, and Composition.
- 5 Classes for Harmony.

8 Classes for Singing.

6 Classes for Single Solfeggio.

8 Classes for Single Solfeggio taught masters.

3 Classes for Concerted Solfeggio.

2 Classes for Opera Instruction.

4 Classes for Comic Opera.

5 Classes for Declamation.

1 Class for Theatrical Deportment.

1 Class for Fencing.

1 Class for Popular Singing.

Evening classes for adults; chorus with accompaniment.

1 Class for Organ.

6 Classes for Pianoforte.

5 Classes for Clavier.

1 Class for Orchestral playing.

4 Classes for Violin.

2 Classes for Violoncello.

1 Class for Double Bass.

1 Class for Harp.

1 Class for Flute.

1 Class for Hautboy.

1 Class for Clarionet.

1 Class for Bassoon.

1 Class for French Horn.

1 Class for Trumpet.

1 Class for Trombone.

There is a branch of the Conservatoire students training for bandmasters in

2 Classes for Harmony and Composition.

1 Class for Cornet-à-Piston.

1 Class for Sax-horn.

1 Class for Saxophone.

2 Classes for Solfeggio.

There is a committee for musical education members, and a committee for dramatic education fifteen members, the director being president.

A library is attached to the Conservatoire superintendence of a librarian and sub-librarian open daily (Sundays excepted) to the student public. It contains ancient and modern works printed, and receives a copy of every new publication.

A museum of musical instruments, ancient and modern, under a curator, is open Sundays and Mondays. Male and female students are instructed separately. Professors are "titulaires and agrégés." They receive higher salaries, the maximum being 2,000fr. The professors for occasional instruction and rehearsals have no salaries. All the expenses of the conservatoire are defrayed by Government. The expense in 1859 was 181,000 francs. Since then it has not diminished. This year 20,000 francs extra were demanded.

There are several provincial conservatoires in connexion with that of Paris; at Lille, founded in 1841; at Toulouse; at Marseilles, founded in 1841; and at Nantes.

The Toulouse Academy is the most important. The director is appointed by the minister, has 2,000fr., and has lodgings found. The professors have 1,400fr., and are named by the prefect on the recommendation of the Government inspector. There are singing-classes (male and female), several classes, two classes for pianoforte, one class for violin, one class for violoncello. It receives a subvention of 5,000fr. from Government. The town pays 100,000fr.

The Lille Academy is chiefly for instrumental instruction. There are classes for bassoon, French trumpet, flute, hautboy. It has a subscription of 100,000fr. The town supplies the rest.

The academies of Metz and Marseilles have no subvention from the state. The former is on a small scale and has been very successful. There are academies of music at Avignon (which costs the town 100,000fr.) and at Nîmes.

Bordeaux, Dijon, Carcassonne, Montpellier, Strasbourg, Valenciennes. All these are independent of the Paris Conservatoire, have no subvention from the state, and are maintained by the municipalities or private associations. An inspector general visits the provincial academies at the expense of the Paris Conservatoire.

With regard to *Secondary and Primary Instruction*, a recent decree (Jan. 30, 1865) has reorganised as follows the teaching of music in the Lyceums and normal schools of the empire:—

ARTICLE I.—Instruction in music is obligatory with all pupils of the primary normal schools. Also in "plain song" for the Catholic pupils, and religious music for those of other communions.

ARTICLE II.—It embraces the following subjects:—

1. The elementary rudiments of music and singing. Reading, writing, and musical dictation.
 2. The elementary principles of "plain song;" elementary instruction on the organ. The pianoforte may be employed as a substitute for the organ.
 3. Elementary study of accompaniment.
- These subjects are divided as follows in three years of study:—

First Year.—Elementary principles of music. Instruction in the delivery of the voice, respiration, and on the classification of voices. Lessons on the clefs of sol and fa, on the major and minor keys, and on the musical measures mostly in use. Theoretical instruction on the other clefs and measures.

Second Year.—Continuation of the exercises, writing music from dictation, execution of pieces for several voices, elementary instruction in plain song, notation, the modes, reading with words, elementary exercises on the mechanism of the pianoforte and organ, the scales in the major and minor keys.

Third Year.—Continuation of exercises in music and plain song, elementary study of accompaniment, specially with a view to the accompaniment of the plain song, reading easy pieces harmonised and the accompaniment of the plain song, the melody given either to the bass or the upper part.

ARTICLE IV.—Five hours per week are devoted to lessons in music and plain song in each of the three years. The time given in the intervals of the lessons to the study of the pianoforte and organ is taken from the hours of recreation and between the church services on Sundays.

ARTICLE V.—The organ, harmonium, and pianoforte are the only instruments employed for musical instruction in the primary normal schools.

ARTICLE VI.—Instruction in music is obligatory in the Lyceums for all the pupils of the inferior classes up to the fourth inclusive. It is optional for pupils of the third class and above.

ARTICLE VII.—The instruction is obligatory in the following subjects:—Elementary principles of music and singing, reading, writing, and musical dictation. The final object of this education should be reading in all the major and minor keys with the times most in use, and the execution of pieces of moderate difficulty for one or several voices.

ARTICLE VIII.—The optional instruction may include, besides the subjects which are obligatory, the elementary principles of harmony.

ARTICLE IX.—Instrumental music will be taught to individuals at the expense of their families.

ARTICLE X.—Two hours a week are devoted in this division to the obligatory musical instruction, Sundays and hours of recreation excepted. The pupils are taught in several courses according to their progress, and not according to the classes to which they may belong.

ORPHEONS OF THE CITY OF PARIS.

A Commission, consisting of musical notabilities, and presided over by a member of the Municipal Council,

examines the questions relating to the teaching of singing in the schools of the city of Paris.

This Commission decides on the method which should be adopted by the professors, regulates the pieces of music which are to be sung by the pupils, examines the candidates for places as professors of music in the schools of the city, and gives judgments on the competitions between the professors elected.

There are 234 schools in which music is taught on both banks of the Seine. The personality of the musical education in the schools is composed as follows:—

Two directors (one for the right bank, one for the left) each at 6,000fr. Two inspectors (one for the right bank and one for the left) at 3,600fr. Forty-four teachers and six supplementary teachers at the following salaries:—Each professor receives 200fr. for each school in which he teaches singing. A professor has the charge of a class in six schools, the ordinary salary is 1,200fr. At the end of five years the pay from each school is 233fr. 33c. At the end of ten years it rises to 266fr. 66c. At the end of fifteen years, to 300fr., which makes 1,800fr. to a professor who has six schools. When a professor has charge of several classes of adults he receives 300fr. per annum, and after five years 400fr. Each school receives three lessons of singing in the week. Twice a month the directors of the right bank and of the left bank, separately, unite the most advanced pupils of the singing classes (children and adults) on Sundays. On Thursday evenings the directors assemble the most advanced male adults, selected by the professors, for a course of higher instruction. Every year the most advanced pupils (children and adults) sing choruses, without accompaniment, at an organised meeting. They number from 1,300 to 1,400 for each bank of the Seine. The city of Paris pays all the expenses of the "Musical Orpheon" of Paris. They amount to about 136,000fr. per annum.

Choral Societies and Free Orpheons.—The choral societies ("Orpheons libres") have extended throughout France a taste and a regard for music. They are not regularly organised, are upwards of 1,200 in number, and receive no subvention from the state.

Many of the societies receive from their respective municipalities a subvention for the appointment of a professor charged with the direction of the music, and room free of expense for practising. Other choral societies are maintained by local subscriptions and honorary non-musical members, who pay from 5 to 10 francs. Two concerts a year are given for the benefit of the honorary members. Other societies are maintained by subscriptions among the members only, which vary from 50 centimes to a franc per month.

The meetings for choral singing and the distribution of prizes attract great crowds, and for that reason are usually held in the open air. In 1862 there were 26 such meetings; in 1863, 34; and in 1864, 41.

1,040 choral societies form an effective strength of 27,500 orpheonists who have taken part this year in the choral meetings. They are frequently assisted by orchestras and bands of wind instruments.

The municipalities derive a large profit from the octroi duties paid by the large concourse of strangers attracted to the towns by the festivals. The city of Lyons received 58,002 francs 17 cents. on the occasion of the Orpheonic meeting in May, 1864. These sums are expended in the purchase of gold and silver medals, given as prizes. Gold medals for different objects are also given by the emperor, senators, deputies, and members of council of the departments.

These festivals are organised by associations of numerous choral societies. The Association of the Seine consists of 28 free Orpheon societies and 25 adherents. It has one annual concert and two meetings; it publishes a journal, and is maintained by its own resources, receiving only a small donation of 500 francs from the Minister of Fine Arts, by way of sanction.

The choral societies of Alsace include those of the

Upper and Lower Rhine. They have large meetings, and receive no subscription.

The Association of Musical Societies of Calvados has been founded only one year. It gave a concert in 1864, and is preparing another for July, 1865.

During eighteen years the choral societies of France have subscribed upwards of a million of francs to charitable institutions by giving concerts for the benefit of the poor. During the cotton crisis the choral festivals for the benefit of unemployed workmen realised 100,000 francs.

INSTRUCTION IN ART.

The following article has appeared in the *Times* :—

Perhaps the most durable and tangible result which the Great Exhibitions of 1851 and 1862 have bequeathed to us is a thorough conviction of the necessity of giving to our manufactures the extra value imparted by elegance of form and beauty of colour. Political purists may affect to doubt whether the cultivation of the taste of the nation and of its manufactures be a legitimate province for the activity of Government; but the point seems practically settled by the large sums of money which are annually voted by Parliament and by the Reports of successive Committees appointed with no friendly spirit, but uniformly ending in approving what they were appointed to condemn. We are committed, for good or for evil, to the development of our taste as a part of the duty of our Government. We have done too much to go back, and the only practical question which remains is in what direction and by what means shall we go forward.

We do not find in the debate of Thursday on the Art and Science Estimate any very practical suggestion on this point. We have established a Museum of such objects as are supposed to contribute to the improvement of Art and Manufacture, which is certainly, whatever may be its utility, one of the prettiest, best managed, and most attractive Exhibitions in London. We have founded a Central School, connected with this Museum, for the instruction of masters and of such pupils in drawing as are willing to pay the value put upon the instruction they receive, a species of opidians or commoners, the future masters being educated at the public expense. We give besides aid, in the shape of pecuniary grants, to some ninety schools in the principal towns of the three kingdoms. Such is our present system, and we seek in vain in the rather warm debates which have been held in Parliament for any suggestion for its improvement. The great battle-field is the South Kensington Museum itself. A violent feud seems to exist on the subject. Mr. Layard maintains, apparently with good reason, that the Museum is a great boon to the metropolis; while Mr. Cox considers it too far removed from Finsbury, very convenient perhaps for the upper ten thousand, but useless to the great mass of the inhabitants he represents. Mr. Bentinck sees in this Museum one of the strongest proofs of the systematic plunder of the country for the benefit of the town, and he takes alarm at the fact that some portions of the iron building, being no longer required, are to be presented to some suburban district to form the nucleus of a new museum. This is a fair specimen of the comprehensive manner in which the support of an institution intended to exercise, and, indeed, having already exercised the most beneficial influence on our manufactures, is discussed. We cannot wonder, if there was nothing better to be said against it, that the attack on the South Kensington Museum proved utterly harmless. Mr. Potter next assailed the Training School—undoubtedly the most useful part of the expenditure for the purpose of diffusing sound art-knowledge. He considers the fees paid by unassisted students too low, and so he moved the reduction of the grant to the Schools of Art throughout the country by £1,000. This also did not appear a very satisfactory measure of reform, and so there is no reason

to be surprised that the Committee did not accede to the proposition.

The weak point of the system lies, we are well convinced, neither in the Museum, which is an ornament to the metropolis, and an institution signally useful to the trade of the country, nor yet in the Training School, which has created and kept alive the highest standard of art-teaching throughout the country, and rescued many schools from ignorant and incompetent hands. The weak point of the system is in the little support that is given to Schools of Art by localities in which they are most valuable and which profit most by their services. The subscriptions raised by the richer inhabitants of the ninety places in which schools receiving aid from Government are established are absolutely contemptible. The whole amount does not, according to Mr. Potter, exceed £1,000 a year. In many places there is no subscription at all, and yet it is amusing to see with what pertinacity the managers of these schools, who do little or nothing for themselves, demand grants from Government, how deeply injured they feel if those grants are not as large as they expect, and how earnestly they press upon others the claims of Art to which they are almost entirely deaf. The truth is, that in Schools of Art that voluntary element which gives so much support to the schools for the education of the poor is almost entirely wanting. The Government does not in this case aid a voluntary movement, but endeavours to originate one in favour of which little or no voluntary support can be enlisted. There is very little help to be counted on from any other source than the fees paid by the working men themselves; and the existence of the system must depend upon whether these fees, together with the aid derived from Government, are sufficient to defray the requisite expenses. The Art Schools are evidently deprived of one great advantage possessed by the schools of primary education. Both classes of schools have, indeed, bodies of managers, but the managers of the schools for the education of the poor have a strong pecuniary interest in their success, and contribute as well as direct, while the managers of Art Schools are little more than recipients of public money, which they are not prepared to supplement by resources of their own. The result is that the master in the elementary school is the servant and under the control of the managers, while in the Art Schools the managers are little and the master almost everything.

We await with some curiosity the result of the new Minute, which seems to be the last effort that can be made on behalf of local art-education in this country. If the aid thus given be found not enough to stimulate local subscriptions, there is no remedy that we can see but to give up altogether the attempt to support local art-education at the expense of Government, and to confine ourselves for the future to increasing the Museum and maintaining the Training School, so that Art may not die out among us for want of skilful teachers. The rest must be left to the energy of the nation. If it turns out that there is not in our manufacturers sufficient public spirit to avail themselves of the assistance which the Government provides for them, it seems hardly reasonable to expect that the community at large should continue to expend in which those for whose profit it is designed obviously take so little interest. Nothing flourishes long in England that rests merely on Government influence. The great manufacturing community of the country have the question fully before them, and they must decide whether they will second the efforts of Government, or leave them to fall fruitless to the ground.

GRAPE CULTURE IN AMERICA.

As the London market has for some time been supplied with fresh grapes, the produce of North America, it may be interesting to members of the Society of Arts to know that more than one hundred years ago the Society was much

occupied with the question of the introduction and culture of the vine in that country. The following is an account of its endeavours at that time to promote this object:—

"Several attempts had been made, but without success, to introduce the vines of the eastern continent into our American colonies, in order to the making of wine; and the Governor of Georgia, in particular, had been fruitlessly at considerable pains and expense on this account there. The Society, however, deeming it not impracticable, and urged by the importance of the question, entered with great spirit into the design of encouraging it, and had pursued their intentions by the offer of various premiums. The first, in the year 1758, proposed the following premium for the wine itself:—'As producing vines in our American colonies will be of great advantage to those colonies, and also to this kingdom, it is proposed to give to that planter, in any of our said colonies, who shall first produce, within seven years from the date hereof, from his own plantation, five tons of white or red wine, made of grapes the produce of the colonies only, and such as, in the opinion of competent judges, appointed by the Society in London, shall be deemed deserving the reward, not less than one ton thereof to be imported at London, one hundred pounds.' This premium was continued to be advertised up to 1765, the period appointed for the bringing in the claims, and then dropped. After the year 1769, a *nota bene* was added to the advertisement, which expressed 'that the method of cultivating vines for wines, and the manner of making wines in different countries, were to be found in Miller's Dictionary, edit. 1758.' During the time this premium was offered, others for the raising vines for wines were also proposed to be given. In 1762 the following advertisement was published:—'A premium of two hundred pounds will be given for the greatest number—not less than five hundred—of the plants of the vines which produce those sorts of wines now consumed in Great Britain, which shall have been properly planted and effectually fenced, secured, and cultivated within any of the British colonies upon the continent of North America to the northward of the river Delaware, considered as one district, between the 1st of 1762 and the 1st of April, 1767; and fifty pounds for the next greatest quantity, not less than one hundred plants.' 'The like premiums were separately offered 'for any of the British colonies on the continent of North America to the southward of the river Delaware.' And the same was also proposed 'to the Bermuda Islands.' To these advertisements was subjoined a *nota bene*, declaring that the person who should be entitled to the premium for raising five tons of wine, as published in the list of premiums, in 1761, should not be entitled to these premiums.' In 1763 the Society thought proper to continue the premium for the planting vines in the colonies to the southward of the river Delaware, and the Bermuda Islands, to the year 1768. In 1765 they also proposed to give additional premiums of two hundred pounds, and fifty pounds, under the like limitations, for the planting the same quantity of vines, actually producing the grapes, which yield those sorts of wines now consumed in Great Britain, between the 1st of April, 1768, and 1st March, 1770. These premiums have not been extended since the time mentioned, because the introduction of vines into America was known to have taken place. The first account of the success of these premiums was in 1763, when Mr. Carter sent a dozen bottles of two kinds of wine from grapes which grew in vineyards of his own planting in Virginia. The one of these kinds was the product of vines brought from Europe, the other of the American wild vines. They were both approved as good wines; and the Society gave their gold medal to Mr. Carter as the first who had made a spirited attempt towards the accomplishment of their views respecting wine in America. In 1767 there were claims made for the premiums on the raising vines, both from the districts to the southward and northward of the river Delaware. But the form of certi-

fication of that to the southward not being conformable to the advertisement, the claim was not allowed. There were two claims for that of the northward; but the claimant who had planted the greatest number of vines having also failed in some essential points of certification, the premium was adjudged to the other. However, in consideration of having planted so great a number of vines as two thousand one hundred, the Society thought fit to give him a gold medal.

"When the cultivation of the vine was first attempted, the vintage was found in many parts to be subject to very frequent miscarriages from the bursting of the grapes, caused by the rains, before they were ripe. But the Society's measures had occasioned trials of the native vines of America, which were before only considered as wild, useless plants, that promised much better success. In 1768 the Society offered medals for the cultivation of the indigenous native vines.

"The following additional awards, for the planting and culture of the vine, were made:—In 1768, £200 was awarded to Edward Antill, Esq., of Brunswick, North America, for vines planted for making wine; in 1769, the Society's gold medal was awarded to the Earl of Sterling, New Jersey, North America, for planting 2,100 sets for wine; in 1771, £50 to Mr. Christopher Sherb, of Carolina, for planting and cultivating a number of vines in South Carolina, and producing wines made of them; in 1772, the Society's gold medal to Mr. Du Menil de St. Pierre, of Charlestown, for planting and cultivating the vines and indigo, and producing silk by foreign Protestant labourers in the interior part of South Carolina.

"The production of raisins in our American colonies was another of the early objects of the Society. In the year 1759 the following premium was instituted:—'To the person, in any of our American colonies, who shall first raise and cure, from his own plantation, and import into the port of London within six years from the 25th of March, 1759, five hundred pounds weight of good raisins, fifty pounds.' There never was any claim made for this premium; nor, as appears, any effort to obtain it. This mode of premium appearing thus not effectual for the purpose, the Society, in the year 1762, changed it to the cultivation of the vines which produced raisins; and advertised as follows:—'A premium of three hundred pounds will be given to the person who shall, on the 1st of September, 1767, have, or be possessed of a vineyard, or plantation, in any of the colonies upon the continent of North America, southward of the river Delaware, consisting of the greatest number of vines—not less than fifty—actually producing the true Malaga grape, from which the best raisins are made. And one hundred pounds for a like plantation, or vineyard, consisting of not less than twenty-five plants, producing the said grapes.' The next year the Society advertised that they proposed to continue these premiums to the year 1770. These premiums do not appear to have had more effect than those for the raisins themselves."

ROYAL SCOTTISH SOCIETY OF ARTS.

At the meeting, on Monday evening, the 10th of April, Charles Cowan, Esq., President, in the chair, a paper, communicated by Mr. ROBERT ARTOUN, F.R.S.S.A., "On an Improved Plan of Drawing Coals, whereby great Speed is attained with a small Expenditure of Power," was read.

The author stated that the weight of the rope used in drawing coals absorbs a great part of the power employed. In deep pits, for every ton of coals drawn, there may be from two to three tons of rope drawn also. The author's improvement consists in hanging another rope, of the same weight and length as the one previously employed, by its two ends, to the under sides of the two cages, and passing it under a pulley at the bottom of the pit, to keep it in its place. By this expedient the rope is perfectly balanced

in every position, one half ascending while the other half is descending, and the engine is absolutely relieved from the burden of the rope, at the mere expense of the friction caused by the weight of the additional rope, which is trifling. Pits, whose depth requires stronger and heavier ropes than could be worked on the present unbalanced system, may be worked (in the author's opinion) on the proposed system successfully, and with engines of moderate power; for the entire weight of the ascending rope and cage is balanced by that of the descending ones, and the engine has nothing to do but raise the coals and overcome the friction caused by the weight of the ropes, cages, and coals. The author showed the simplification which this system permits of being introduced into the winding apparatus. Instead of the lofty pit-head frame, and its two pulleys, he places a single large pulley over the mouth of the pit, corresponding to one at the bottom. The drawing rope is to be passed over this pulley, and the cages are to be hung to its two ends. This rope, connected to the lower rope by means of the two cages, may be considered as an endless band stretched between the two pulleys, and completely balanced in every possible position. The steam-engine, by means of a connecting rod working a crank on the shaft of the upper pulley, sets it in motion either way; and the pulley, by means of the friction betwixt its surface and the rope, communicates that motion to the rope and the cages with their loads.

The paper describes its application to a pit 300 fathoms deep, in which two tons of coal are drawn at a time. It is there pointed out that the winding friction is the only unproductive work, and amounts to no more than three per cent.; while 97 per cent. of the power derived from the steam-engine is productively employed. The paper next shows how it may be applied to drain, by means of tube, the "drowned out" mines of Tyneside, yielding 5,000 gallons per minute. The unproductive power in this case, it is stated, would only amount to two per cent.

Besides these advantages, there are said to be others which result from the engine being connected with the drawing rope by the friction of the pulley, instead of by solid shafts or toothed wheels. If the engine is forced into violent action, which would endanger the rope on the old plan, it will merely cause the pulley to slip under the rope. If the cage should meet with an obstacle in the shaft, the rope again slips on the pulley and no damage is done. But the chief advantage occurs when the engine does not stop when the cage has reached the top of the pit. The result would be, under the present system, the dangerous accident of over-winding; but, in the proposed system, as soon as the lower cage rests upon the bottom, and the rope and upper pulley are relieved of its weight, the friction is reduced *pro tanto*, and the pulley slips under the rope, without having power to raise the cage above the landing, and no damage whatever is done to the winding gear, or to the individuals who may be in the cage.

As the slipping of the rope on the pulley prevents breakage in the shaft, a much higher speed than is considered safe at present can (says the author) be maintained. As there can be no over-winding, this higher speed may be maintained till the cage has almost reached the surface. This is a saving of time. Again the engine stops, with the steam nearly full on, balancing the loaded cage; thus there is no occasion for struts for the cage to rest upon, and the time wasted on them is also saved.

This system is supposed to be peculiarly adapted to the use of safety cages. There is a screw which moves the lower pulley, and tightens the rope, thereby compressing the springs of safety cages and keeping the clutches, or claws, clear of the guide rods. This removes the only objection which is now urged against the use of safety cages, as it permits them to have powerful springs to overhaul the broken rope, without there being any danger of their catching the guide rods while the rope is entire.

Fine Arts.

LOST PICTURE FOUND.—M. Triccia, of Florence, a painter and restorer of pictures, has made a fortunate discovery. He was engaged by an amateur to examine a collection of miscellaneous matter, when he discovered a large canvas, eight feet long and more than six feet high, which struck him immediately as a work of importance, and he succeeded, after some trouble, in deciphering the name of the painter, "Luca Signorelli." Such a work is specially mentioned by Vasari, who says that Signorelli visited Florence to study the great masters of that school, and painted for Lorenzo de Medici a picture called "The Naked Gods," which had a very high reputation. Vasari adds, "we have no information whatever about the fate of this picture." M. Triccia declares that there is no doubt that the work which he found neglected in a loft is that to which the critic refers.

NEW GALLERY OPENED IN THE LOUVRE.—The directors of the Louvre have just opened another series of rooms containing pictures of the French school; amongst which will be found works by Fouquet, De Courtois, Ambroise Dubois, Jean Cousin, and others of the Burgundian school; an excellent collection by Clouet, and other artists of the fourteenth, fifteenth, and sixteenth centuries; and a large number by Lesueur, Lahire, Simon Vouet, Bon Boullogne, Restout, Jean Mommier, Charles Lafosse, Joseph Vernet, Hubert-Robert, Casanova, and others. The new gallery has been called after Eustache Lesueur.

THE BONAPARTE MONUMENT IN CORSIKA.—On the 15th ult., Prince Napoleon presided over the inauguration of the grand monument raised at Ajaccio to the memory of Napoleon Bonaparte and his family. The Emperor is on horseback surrounded by his four brothers, and all, by a strange caprice, very unusual in France, are dressed in Roman costume. The equestrian statue is nearly ten feet high, and the others about seven feet each; the base is raised more than twelve feet above the level of the soil. The statues are cast with bronze furnished from cannon taken in the late Italian campaign, but two winged Victories, placed in the basement, are of marble. The entire monument is about a hundred feet in length and twenty-five feet in height. The general arrangements were entrusted to M. Viollet le Duc, and the sculpture by MM. Barye, sen., Thomas, Jean Petit, Maillet, and Dubray. The day of the inauguration was a grand fête. The population of Ajaccio is only 14,000, but 40,000 people were collected on the occasion. Prince Napoleon delivered an eloquent address, which occupied an hour and a half.

EXHIBITION OF RETROSPECTIVE ART.—The Paris Union Centrale des Beaux-Arts as applied to industry, whose establishment in the Place Royale has been noticed in the *Journal*, has decided that the Exhibition of Industrial Art which is to open under its auspices in the Palais de l'Industrie on the 10th of August, shall include retrospective art as well as that of the present day; and has just issued an invitation to collectors for contributions. The Council expresses its conviction that such a collection will be of great service, at the time when all the world is preparing for the Universal Exhibition of 1867. The retrospective exhibition is to include objects of all past epochs without exception, antique, mediæval, and renaissance.

ART PATRONAGE IN MEXICO.—The Emperor Maximilian has always been a patron of art; when Archduke the Saxon sculptor Knauer executed busts of Goethe, Schiller, Shakespeare, Dante, and Homer, for the chamber of Miramor. The Emperor has just commanded of the same artist busts in Carrara marble of Alexander the Great, Julius Cæsar, Augustus, Antoninus Pius, Marcus Aurelius, Charlemagne, Charles Quint, Napoleon I., Napoleon III., and Humboldt, for the Imperial Palace of Mexico.

A BORN ARTIST.—M. Charles Ooms has just received the first prize of excellence in painting at the Royal Academy at Antwerp. Seven years ago he was engaged in minding his mother's cows, in a village in the Campine, but instead of leaving the animals to the best pasturage, he occupied himself in making innumerable sketches of them. His mother complained of the boy's idleness to her daughter, who was in service in Antwerp, and the latter, in her turn, spoke to her master on the subject. This caused an inquiry to be made into the matter, and the sketches were thought sufficiently promising to warrant the education of the lad, who was utterly without any kind of instruction. M. Teichman, the Governor of Antwerp, and his secretary, M. Thielens, recommended the boy to M. de Neyser, the director of the academy in that town, who received and protected him, with the result already mentioned.

Manufactures.

NEW IRON BRIDGE.—There has been just completed, in the yard of the Regent's Canal Ironworks Company, a remarkable iron bridge, which is the largest yet constructed on a system invented by Mr. A. Sedley. The structure in question has been made to the order of the Indian Government, and is designed to be erected in India. The leading feature of the new principle is that, without the necessity of any subaqueous works, or the erection of any intermediate towers or piers, the bridge can be built to cross in a single span any river or chasm up to an extreme width of 500 yards, or 1,500 feet. The bridge just finished is of 75 feet span and 14 feet wide; its total weight is 22 tons, including the roadway, and it will support a nominal strain of four tons per sectional inch, but really a greater weight. Two great cantilevers, or wedge-shaped girders, are built up piece by piece till they are projected from opposite sides of the chasm or river which is to be bridged over, and extended till they approach within a distance something less than a third of the whole span. Across this space a central girder is thrown, which, while it completes the continuity of the bridge, acts, when fixed in position and riveted down, as the key-stone, so to speak. The wedge-shaped girders which project from either side of the stream are at their wide ends embedded and built into massive piers of masonry on the shores. The base of the wedge is fixed by iron tugs, in an upright position; the central arm of the girder supports the actual roadway of the bridge; the lower arm, stretching to the point of the girder, becomes a bracket support; and the upper arm passing over the summit of the upright end, which makes the thick end of the wedge, is extended backwards as a tension bar, and anchored firmly in the earth, thus giving suspensory support to the central arm, which attains a perfect rigidity. Upon the piers the whole strain is thrown. The roadway is constructed of the iron-buckled plates, invented by Mr. Mallet, which have done such good service on Westminster-bridge. For the hill-roads in India the bridges constructed on Mr. Sedley's new system seem well adapted.

Commerce.

THE WHITEHALL AND WATERLOO PNEUMATIC RAILWAY.—It appears that arrangements have now been made which will admit of the commencement of the works of this proposed railway immediately on the necessary Parliamentary powers being obtained. The Bill has passed the Commons, it is now unopposed in the Lords, and in a few days it may be expected to receive the Royal assent. The proposed line will commence at an open station to be formed in Great Scotland-yard, and be con-

tinued in brickwork under the Thames Embankment to the river; across which it will be carried in a watertight iron tube, encased in cement concrete, laid and fixed in a channel dredged out of the bed of the river. From the river the line will be continued in brickwork under College-street and Vine-street, to a station convenient for the traffic of the York-road and the Waterloo terminus of the South Western Railway. The steepest gradient will be 1 in 30. The trains will be worked to and fro by pressure and exhaustion alternately, and at intervals of from three to four minutes from each end; a frequency of despatch hitherto unattempted. The carriages will be as commodious, as well lighted, and as completely fitted for the comfort of the passenger, as those of the Metropolitan Railway. The iron tube will be made by Messrs. Samuda, and the laying of the tube and the other works will be undertaken by Messrs. Brassey and Co. The principle upon which the line will be worked will be the same as that adopted on the experimental railway in the grounds of the Crystal Palace. The machinery will be on the Surrey side, at the York-road station. The whole of the works are to be completed in twelve months from the date of the commencement. The cost of the undertaking will be about £180,000. The pneumatic system, by which air is applied to railway propulsion and the incumbrance of the locomotive is got rid of, differs materially from the former atmospheric system. Under the new system, the train is wholly within a tube or covered way (through which it is rapidly propelled by the pressure of the air behind it), so that not only are all the difficulties attending the continuous valve and the consequent leakage avoided, but the advantage of working with greatly reduced pressures, and with proportionate economy, is obtained. Thus, while the old system necessitated a pressure of from 120 ounces to 160 ounces per square inch to move the train—under the new, a pressure of 3 ounces or 4 ounces per square inch is found sufficient. Indeed, in its present form the pneumatic system is simply an adaptation of the process of sailing to railways; the wind being produced by steam-power, and confined within the limits of a tube.

TUNNY FISH.—This fish, which, when pickled, is much esteemed in France as a *hors d'œuvre* or relish, is generally rather scarce, but recently an enormous quantity were taken in the waters of a little fishing village called Sausset, between Port de Bouc and Marseilles, and accounts from the last named place say that the number brought to market there has been about fifteen hundred a day, and that the quantity remaining still in the *madrague*, or great net used for catching this fish at Sausset, is so great that it is feared a large portion will be lost for want of means of preserving the fish quickly enough. The single haul at which all these fish were taken is believed to have yielded about 40,000 francs (£1,600) to the society of fishermen at Sausset, and that after a certain amount is withdrawn, according to established custom, for the reserved funds of the society, each fisherman will have about £24 for his share of the proceeds.

Colonies.

TELEGRAPHS IN NEW SOUTH WALES.—The telegraph line between Braidwood and Araluen has been completed, and opened for messages. The only extension at present in progress is that from Queanbeyan to Cooma, of which a length of about fourteen miles is finished. A contract has been taken for the formation of a telegraph line from Deniliquin to the borders of South Australia, to afford direct communication between Sydney and Adelaide, but the work has not yet been commenced. No new lines are proposed in the estimates for the present year. Applications have been made to the Government for the extension of the telegraph to various districts; but as all the more important towns in the colony are now con-

nected by the wire with Sydney, it is made a condition of further extensions that residents in the districts desiring the telegraph should guarantee to the Government a return of five per cent. upon the outlay for five years.

NEW SOUTH WALES COAL.—The quantity of coal entered at the Sydney Customs, from 17th February to 20th March, 1865, inclusive, was 13,218 tons, while the shipment from the various mines on the Hunter, Newcastle, for the same period, amounted to 16,875 tons.

THE REVENUE OF TASMANIA appears to be not very flourishing. The total received from all sources for the past year was £181,074, as against £183,455 in 1863. In the Custom-house the decline was £2,809.

SIROCCO AND BUSH FIRES IN VICTORIA.—On 27th February a fierce sirocco wind set in from the north-west, exceeding in its velocity and overpowering heat any that has been experienced for the last fourteen years. It was felt in a nearly equal degree all over the country. Extensive bush fires speedily commenced, and in Melbourne the heavy smoke filled the city like a thick fog; breathing became difficult, and except in houses whose inhabitants had closed every window and door betimes, a sense of prostration prevailed. At Ballarat the heat reached 99 degrees, and bush fires raged from Spring Hill and Learmouth to the border of Bullarook Forest. From Geelong to Ballarat was nearly a line of fire, and much damage was done to houses, crops, and fences. In the country round Daylesford similar disasters occurred. The large agricultural district of Kyneton was severely visited, and a long list is recorded of homesteads, growing crops, stacks, well filled barns, and fencing destroyed by the calamitous fire. Steps have been taken for the relief of the sufferers. Parliament has been asked for £50,000 to help the more completely destitute, and the colony is being canvassed for subscriptions in aid of the Kyneton farmers, of whom many are completely ruined.

WINE-MAKING IN SOUTH AUSTRALIA.—The past season has been very dry for the grapes, and will affect the weight of the yield; but, with careful management, a very superior wine may be produced. The wine-growing interest is now assuming a really important character from the number of persons engaged in this industry, and from the large and increasing capital at stake. Considerable excitement prevails amongst vignerons in consequence of the late colonial government having intimated their willingness to allow free distillation from the produce of the vine at least. Should the present restrictions upon converting wine into spirits be removed, a great impulse would be given to the vineyards of this colony.

Publications Issued.

A RECORD OF THE PROGRESS OF MODERN ENGINEERING, 1864, comprising civil, mechanical, marine, hydraulic, railway, bridge, and other engineering works, with essays and reviews. By W. Humber, Assoc. Inst. C.E., and M. Inst. M.E. (*Lockwood and Co.*) This volume contains detailed drawings to a large scale of many important works, among which will be found the following:—The entrance to the Mersey Docks, Birkenhead, including the low-water basin, details of the sluices and flushing apparatus, the hydraulic machinery for working the shuttles, also the hydraulic machinery for opening and closing the lock gates; the bridge over the fifty feet lock, with the hydraulic machinery for moving the same; the pumping engines, engine house, and accumulators; also the landing-stage in the low-water basin, &c. The Charing-cross Railway Station, with full detailed drawings of the roof; viaducts and bridges on the Great Northern Railway; College-wood Viaduct on the Cornwall Railway; the principal details of the Winter Palace at Dublin; the railway-bridge over the Thames at Blackfriars; full details of the Greenock-docks; viaducts on the Merthyr.

Tredegar, and Abergavenny Railway; and other engineering works. The letter-press comprises articles on the formation of harbours and breakwaters, with a description of the works at Greenock; a full description of the arrangement of the Birkenhead Docks and hydraulic machinery; articles on iron permanent way, &c., &c.

Notes.

EXHIBITION OF INSECTS.—A novel kind of exhibition is announced to take place in the Palais de l'Industrie of Paris, in August and September. The Central Society of Agriculture has conceived the idea of showing to the public a collection of insects useful for their productions—such as silk-worms of all kinds, bees; insects producing colouring matter; edible insects; and insects made use of in medicine; and, secondly, of such as are mischievous to various crops—as cereals, the vine, citrons, and other plants made use of in industry, green crops, and other edible plants, fruit trees, forest trees, timber and wood; and, lastly, of parasitic insects of all kinds. The edible insects will include the eggs of the Hemiptera of Mexico, with the bread made from the same; the larvae of *Lucia* and China; locusts; and Polynesian spiders. The Acclimatisation Society and the model farms maintained by the Imperial Government will furnish a considerable number of living specimens in some of the divisions; but there is little doubt that in others the public must be content with the "still-life." The Minister of Agriculture and of Public Works has accepted the presidency of the Committee of Organisation, which includes several persons of scientific eminence. The Exhibition is announced to open on the fifteenth of August.

LITERARY AND ARTISTIC CONVENTION BETWEEN FRANCE AND BAVARIA.—International property in works of art and intellect is rapidly extending, and cannot fail to exercise considerable influence, not only on artists but on the general condition of education and taste. By the convention concluded in March last, but just now promulgated, the artists and authors of each country will enjoy in the other the same privileges and protection as if they had been first published in that country, and all works of the kind referred to will be allowed to pass duty-free between the two states on the production of certificates of their origin. The convention comes into operation on the first day of July in the present year, and is applicable to any of the states of the Zollverein that may desire to subscribe it.

THE ERUPTION OF ETNA.—The eruption of great volcanoes is an object of such terrible magnificence, that few observers are sufficiently masters of their judgment to form any very correct notions of the various circumstances of the phenomena. In the present instance, however, M. Fouqué, a French *savant*, has studied this convulsion of nature for fifteen days under great difficulties and privations, and has communicated the results of his observations to his friend, M. Sainte Claire-Deville, who has published them to the world. The eruption commenced on the last night in January, two shocks of earthquake having occurred during the previous day. At the moment of the breaking out of the convulsion there was another and very violent shock, which was, however, only felt on the north-east side of the mountain. At Lavina, near Piedimonte, the inhabitants were so terrified that they fled from their houses and spent the night in terror in the open air, while at Catania, on the other side of Etna, the earthquake was scarcely felt. The eruption commenced on the north-east side, at about 1,800 yards above the level of the sea, and 500 yards from an old crater, Monte Frumento, which is itself at the base of the principal volcano. As soon as the earth was opened, the lava began to pour forth, and in four days the stream was nearly four miles long, full half that in breadth, and is

any places not less than from thirty to sixty feet in depth. The river of fire flowed down a part of the mountain, having an average inclination of four or five degrees, destroying everything in its course, till it encountered another old cone known as Monte Stornello. Here the lava was divided into two streams, one descending gently on the west of Stornello, while the other precipitated itself into a deep and narrow valley, situated between Monte Stornello and the chain of hills called *Monte de la Boffa*. Here a cascade of fire, bearing on its surface masses of solidified blocks, fell over a precipice more than 150 feet deep with fearful noise; the valley was soon completely filled, and the stream of lava continued its course for nearly two miles more, and stopped at the place of an old lava flood called the *Sciara de la Socia Vacca*, at an altitude of about 2,600 feet above the sea. The western stream continued its course, and came itself divided into two; one of these continued descending till the 21st, and the other till the 25th of February, when the head of each was arrested, but small lateral streams continued to be produced at intervals. On the 6th of March another stream burst forth from the east of the craters, and was still increasing and advancing rapidly when M. Fouqué wrote. This will give some idea of the enormous power and extent of these hidden fires, which in a few days can fill up valleys and change the face of a country for miles. But M. Fouqué's account of the craters themselves extends the idea of the terrible and of such convulsions. The craters, he says, are seven in number; five of them lie in a large elliptical space, each crater being not at the top but at the side of a cone or hill, from 150 to 200 feet high. The other two craters are on the outer side of one of these cones. The lip containing the five craters is described as forming what was one great crater, the ground being burst open and split in all directions. This great oval crater, which closed in on all sides but one, whence escapes the river of lava already mentioned, is about 1,800 feet long, and 800 feet wide at its narrowest part. From the base of the cone of *Monte Frumento* to that of the nearest crater exists a tremendous fissure, about 1,800 feet in length, generally fifty feet wide, and in some places of immense depth. This huge crack is partly filled with blocks of chilled lava, the effect of the snow, which had accumulated to a considerable depth. Where the lava stream was most dense the heat was so great that the largest pines were entirely carbonized, even at a distance of sixty feet from the fiery river. This account enables us to form some slight idea of the convulsions which subterranean fire has created at various times on the surface of our globe.

GIGANTIC ASPARAGUS.—Enormous heads of asparagus were recently appeared in the Paris market, and many theories have been made respecting the mode of their production. It is said that a large grower was recommended to cultivate the plants not together, as in the ordinary manner, but dispersed amongst other vegetables in his garden, and that the success was beyond all his expectations. The cause of this is not evident, but it may be suggested that probably the experiments were tried in a very warm soil in the south of France, which supplies us with an enormous quantity of fruit, peas, and asparagus. Having succeeded in obtaining a gigantic growth, the grower tried a further experiment. He placed over the shoot, as soon as it appeared above ground, a glass bottle, or rather short tube with a bottom to it, pressing it latter down as far as possible into the ground. The consequence of this treatment is the production of enormous heads, each sufficient to make a dish of itself, and some instances weighing nearly a pound. This colossal asparagus is said to be equal in flavour and as tender as the finest known kinds produced in the ordinary manner.

LOCOMOTIVES ON COMMON ROADS.—Some time since, an experiment was tried at Nantes, which was recorded in the *Journal*, with the view to the establishment of steam omnibuses on the ordinary road. The first essays were made with an experimental machine, but recently the

first trial of a new one was made in the presence of the Mayor and some of the principal people of the place, who filled the omnibus attached to the locomotive. The engine, of eight-horse power, weighs seven tons with its coal and water; it is more than eighteen feet long and nearly six feet wide outside the wheels. The journey was performed without interruption, with the exception that in one place too short a turn was taken and the locomotive had to be unhooked from the omnibus before the error could be rectified. The 29 kilometres between Nantes and Nant were performed in two hours, the locomotive stopping twice to take in water. The steam omnibus was to ply regularly after that day between the two towns.

HOME FOR APPRENTICES.—Mr. Hartley, of the Westminster Marble Works in Earl-street, London, has founded a home for boys, who are taken as apprentices, and placed in a small house, in which a person resides connected with the works, who acts as a master; his wife is the superintending matron; and the control of these lads is placed in their hands. They are called in the morning to go to their work; they return at stated times to their meals, which are always ready for them. There is thus no time lost. After the work is over there are books and newspapers for them to read, or occupation is found in writing and drawing. They are allowed full liberty of ingress and egress, being fined, however, if not in by a stated time, which varies according to the season, and they are allowed a small sum a week for pocket-money; they are thus placed in a position which must have a very material effect in qualifying them to fulfil their duties properly when arrived at manhood. The boys are taken at about thirteen or fourteen years old, and retained until twenty-one, at which age they ought to be able to take care of themselves, and make room for others; and during this period they have all the advantages of a home, and at the same time a surveillance is exercised over them which others in the same station of life have not at their own paternal homes. This institution is said to have been found exceedingly advantageous, not only as an industrial school, but to the master who has founded it, for on a comparison made by Mr. Hartley of the loss sustained by him during a year, taking twelve boys of the Home and twelve apprentices living at their own homes, he found that the loss by absence amounted in the whole to but 11s. 3d. from the college boys; whereas, from the apprentices living with their parents, the loss on the same account exceeded £40 during the same period. Mr. Hartley's proposal is to establish similar institutions throughout the country. There appears to be little or no expense attending them, such as is usually the case with Reformatory Institutions. A small house, at a low rental, capable of containing about fifteen lads, is amply large enough. In fact they might be self-supporting; for employers would be willing generally to pay for the board of their apprentices, rather than receive them into their own houses—this being the great objection to taking them at all.

Correspondence.

ON THE WEAR AND TEAR OF STEAM-BOILERS.—SIR,—As Mr. Paget has omitted (in his last letter) to identify the supposed equivalent passages of his double-barrelled letter, I fancy (but I may be wrong) that my priority is established, as I expected it would be, in the publication of the leading causes of the furrowing and pitting of steam-boilers, which form the basis of his paper. About the stay-bolts, mentioned incidentally by myself, it seems as if he has just succeeded in tracing a prior publication by Mr. Colburn, which certainly presses rather closely upon me. But, if he knew of this before, why did he not acknowledge it in his paper? And if he did not know of it, why did he not acknowledge my publication? It is very likely Mr. Colburn sent me the paper referred to,

just as Mr. Paget sent me a copy of his paper on boilers; but I don't read all that I get in this way. You know the old proverb:—"Though you may take a horse to the water, you cannot make him drink." But, on Mr. Paget's own principles, he must have read what I have written and quoted in your columns for his edification, though he did omit to acknowledge it.—I am, &c., D. K. CLARK.

GRANTS OF PROVISIONAL PROTECTION.

- Animal charcoal, revivification of—1336—G. H. Ogston.
Animal charcoal—1409—K. Muller, A. T. Weld, and J. F. Powell.
Bedsteads—1379—C. Copus.
Bottles, flasks, stoppers, &c.—1320—S. T. Garrett.
Bottles, securing corks or stoppers in—1373—R. A. Brooman.
Calico-printing—1420—J. Dale and A. Paraf.
Cannon, rifling muzzle-loading—1332—W. Spence.
Coal gas, purifying—1386—W. Davey.
Cotton presses—1423—G. Ashcroft.
Cotton-spinning—1383—T. Marsden.
Dish-covers, &c., wire gauze—1401—D. Powis and H. Brittain.
Distilling apparatus—1393—J. A. Coffey.
Dust, apparatus for collecting—909—E. Leak.
Electricity, production and application of—1412—H. Wilde.
Envelopes—1416—H. Gibbs.

- Fabrics, brocaded and ornamental, weaving—1313—D. Hillas.
Fabrics, woven—1316—T. Smith and H. James.
Fire-arms, breech-loading, and cartridges—1308—J. R. Cooper.
Fire-arms, breech-loading—1382—S. Ebrall.
Gas-burners and chimneys—1334—W. Clark.
Gas meters—1395—W. Smith and G. Brown.
Goat's hair, application of in imitation of human hair—1311—Rushton.
Hats, fur or felt, machine for fulling—1314—E. L. Girard.
Horse-shoes—1025—W. Clark.
Hydraulic cranes—1421—H. A. Bonneville.
Iron girders, casting—1304—J. Goodwin.
Knitting machines—1397—E. Attenborough, S. Mellor, Blackburn.
Land-cultivation, machinery for—1104—D. Greig.
Letter-clips—1354—H. E. Dixon.
Locks—1406—W. Hodson.
Locomotive engines—1358—W. Montgomerie.
Looms—1417—T. Calvert and D. Montgomery.
Mangles—1418—H. Nuan.
Manumotive carriages—1388—G. Read.
Manure, liquid, apparatus for distributing—1369—C. S. P.
Nitrogen and sulphur, obtaining compounds of—1396—T. and M. D. Rucker.
Oil, &c., raising from deep wells—1392—W. E. Newton.
Ovens for bread-baking—1346—J. Daughish.
Paper-hangings—1399—J. Wylie and J. Rew.
Photographing on wood, &c.—1174—W. H. Smith.
Pile-driving machinery—1378—W. Easie.
Piles, machinery for cutting off the upper parts of—1406—J. Slater.
Ploughs—1326—J. Eddy.
Printing machines—1344—R. and H. Harrild.
Railways, communication between passengers and guard—W. Chubb and S. Fry.
Railways, securing rails on permanent way—1306—W. T.
Refrigerators—1405—J. H. Johnson.
Saw-mills—1340—G. Ennis.
Screws and screw-drivers—1387—A. V. Newton.
Screw-cutting apparatus—1411—E. McNally.
Sewing machines—1337—J. Laing.
Sewing machines—1384—H. de Mornay.
Sewing-machines—1407—J. M. Clements.
Stays, corsets, &c., fastening supports of—1338—R. Langish.
Steam-crane—1342—C. J. Appleby.
Time-pieces and clocks—1415—H. Adler.
Water-gauges and cocks—1330—A. Weir.
Weaving, power looms for—1307—W. Jamieson.
Yarn, machine for tying hanks of, previous to dyeing—Caldwell.
Yarns, dyeing and sizing—1413—I., W., and J. Holt, and J.

Announcements by the Council.

MUSICAL EDUCATION COMMITTEE.

This Committee are now meeting once or oftener in the week. They have taken evidence from Sir George Clerk, Bart., Mr. H. F. Chorley, Mr. Otto Goldschmidt, and Mr. Lucas, the Principal of the Royal Academy of Music, which will be published in the *Journal*.

FINAL EXAMINATIONS, 1865.

The following alterations and additions should be made in the list of successful candidates :—

Omit 875—Ashmore, Isaac, 18, St. Thomas's Young Men's Christian Inst., pupil teacher.

After 869—Bradbury, Edwin, omit Arith. (3d), he not having worked a paper in that subject.

For 1338—Fielding, John, 17, Bradford M.I., clerk, Arith (2d), read 1837, Alfred Goulton Hooper, 18, Bradford M.I., banker's clerk—Arith. (2d)

Proceedings of the Society.

CONVERSAZIONE.

A Conversazione took place at the South Kensington Museum on Wednesday evening, the 14th inst., when about 3,700 members of the Society and their friends were present. The company was received on entering by Mr. William Hawes, Chairman of the Council. The bands of the Royal Artillery and of the Coldstream Guards were in attendance, and performed selections of music during the evening.

The exhibitions of Portrait Miniatures, and of the Raphael Cartoons were open, and excited considerable interest.

FOURTEENTH ANNUAL CONFERENCE.

The Fourteenth Annual Conference of the Representatives of the Institutions in Union, and the Local Educational Boards, with the Council of the Society, was held at the Society's House on Wednesday, the 14th inst., at 12 o'clock, noon. WILLIAM HAWES, Esq., F.G.S., Chairman of the Council, presided.

The following is a list of the Institutions and Local Educational Boards represented at the Conference, with the names of their respective representatives :—

Aldershot and Farnham Board of Education	Mr. Barrow Rule.
Alton Mechanics' Institution.....	Mr. William Curtis, President.
Ashford Mechanics' Institution...	Mr. Henry Whitfeld, President.
Banbridge (Ireland) Mutual Improvement Society.....	Mr. J. Baxter.
Banbury Mechanics' Institute ...	Mr. R. Heygate Brooks, Hon. Sec.
Berkhamstead Mechanics' Institution	Rev. J. Hutchinson, President.
Blackburn Literary, Scientific, and Mechanics' Institution ...	Mr. R. H. Hutchinson.
Bradford Mechanics' Institute ...	Mr. W. E. Smith.
	Mr. J. G. Best.
	Rev. C. F. Hildyard, President.
Bury Athenæum	Mr. J. M. Wike, Vice-President.
	Mr. W. Lawson, M.P.
Carlisle Mechanics' Institution...	Mr. E. Potter, M.P.
Chatham, &c., Mechanics' Institution	Mr. H. G. Adams.
	Mr. H. P. Mann.
Christchurch Mechanics' Institution	Mr. Joseph Clark, R.A.
	Rev. Z. Nash.
Faversham Institute	Mr. F. W. Monk.
	Mr. J. A. Anderson.
Gilford (Ireland) Young Men's Mutual Improvement Society.	Mr. W. R. Masaroon.
Glasgow Institution	Mr. Alexander Craig.
Hastings Mechanics' Institute ...	Mr. C. J. Womersley.
	Mr. Joshua Huggett.
Hertford Local Board	Mr. J. S. Foster, Secretary.
Hitchin Mechanics' Institution...	Mr. Joseph Pollard.
Huddersfield Mechanics' Institution	Mr. Hiley.
	Mr. Stavenhagen.

Hyde Mechanics' Institution ...	Mr. Thomas Ashton, President.
Kent Association of Institutes ...	Mr. W. G. Adams. Mr. F. W. Monk.
Lancashire and Cheshire Union of Institutes	Mr. Councillor Rumney Dr. R. M. Pankhurst. Mr. Thomas Lawton.
Lichfield Free Library and Museum	Captain Dyott, Chair- man.
Llanelly Mechanics' Institution	Mr. W. H. Nevill, President. Mr. R. T. Howell, Vice-President. Mr. L. D. Bevan.
London, Bank of England Library and Literary Association	Mr. John Coe.
„ City of London College	Rev. R. Whittington. Mr. F. Reynolds.
„ Greville House, Pad- dington	Mr. Bright. Mr. Faulkner.
„ Mechanics' Institution	Mr. T. J. Pearsall. Mr. S. Vallentine.
„ „ Local Board	Mr. T. A. Reed. Mr. E. Hay Currie, Hon. Sec. Mr. H. H. Sales.
„ Metropolitan Association	
„ St. George's and St. James's Westminster Local Board	Rev. G. B. Macilwain.
„ St. Margaret's and St. John's (Westminster) Local Board	Rev. W. S. Bruce. Mr. J. A. Gosset.
„ Walworth Literary and Scientific Institution	Mr. J. S. Noldwitt.
Oldham Lyceum	Mr. J. T. Hibbert, M.P. Mr. John Platt.
Peterborough Mechanics' Insti- tution	Mr. J. F. Bentley, President.
South Staffordshire Association...	Mr. John Jones.
Smethwick, Messrs. Chances' Library	Mr. F. Talbot.
Yorkshire Union	Mr. Barnett Blake.

The Secretary read the following

**REPORT TO THE COUNCIL OF THE SOCIETY FOR
THE ENCOURAGEMENT OF ARTS, MANUFACTURES,
AND COMMERCE.**

GENTLEMEN,—In reporting to you the Proceedings of the Society in connection with the Union of Institutions for the past year, I have the pleasure to record that Walter Slater, of the London Mechanics' Institution, one of the successful candidates of last year, has, after a competitive examination before the Civil Service Commissioners, obtained an assistant clerkship in the Privy Council Office, the nomination being placed at the disposal of the Council by Earl Granville, one of the Vice-Presidents, who has thus evinced the continued interest which he takes in promoting the success of the Society's proceedings. Year by year it has been my duty to record an increase in the work of the Union, and this year forms no exception; indeed, there has been a larger increase in the numbers examined at the Final Examination than in former years. The number of candidates examined this year, is 1,199, being an increase of 131 over

1,068 examined last year, while the increase of last year over the previous one was only 112.

The number of local centres at which the Examinations have been held is 100, where the Local Boards have conducted the Society's Final Examination of the 1,199 candidates who worked papers this year. The number of papers worked has been 1,744, as compared with 1,540 last year, showing an increase of 204; and the Society's examiners have on these papers awarded 1,351 certificates, viz., 315 first-class, 519 second-class, and 517 third-class, leaving 393 to which the examiners have not thought it right to award any certificates.

The corresponding result of last year's Examination gives the total certificates awarded as 1,222, divided into first-class, 236; second-class, 479; third-class, 507, with 318 papers to which no certificates were given.

Included in the above total of candidates for the present year were 35 female candidates, of whom 26 obtained certificates.

The detailed results of the Examinations, of which the above is a summary, are given in Table II., page 511, which shows the manner in which the different subjects have been selected by the candidates.

The Prince Consort's Prize of 25 guineas, graciously continued by Her Majesty the Queen, has been won this year by Thomas Healey, of the Burnley Mechanics' Institution, a book-keeper, who in the present year and during the three preceding years has obtained the greatest number of first-class certificates, viz.:—

- 1862. Arithmetic—First-class Certificate.
- „ English History—First-class Certificate, with Second Prize.
- 1863. Book-keeping—First-class Certificate.
- 1864. Algebra—First-class Certificate, with First Prize.
- „ Mensuration—First-class Certificate, with Second Prize.
- „ Chemistry—First-class Certificate, with Second Prize.
- 1865. Music—First class Certificate, with First Prize.
- „ Animal Physiology—First-class Certificate, with First Prize.

The number of prizes awarded this year has been 51, as compared with 55 last year, and the money amounts in the two years (1864 and 1865) are respectively £217 5s. and £211 5s. This is exclusive of the Royal Horticultural Society's prize of £5 which has been awarded. In reference to prizes, I must not omit to mention that one only of the five prizes offered by the Royal Horticultural Society, for the encouragement of gardeners to make themselves acquainted with the scientific and botanical principles in which their practice should be founded, has been taken. A few competitors only appeared, but it must be borne in mind that these prizes were offered after the Society's Programme for the year had been published, and

* These Examinations were held at a later date, on papers of a similar character, prepared by the Examiners of the Association.

thus but short and insufficient notice could be given.

In the Appendix to this report will be found the remarks of the examiners on the character of the present year's Examinations. The Tables show the occupations, actual or intended, of the various candidates in respect of whom returns were received as intending to be examined, some of whom, however, were unable to fulfil their intentions, leaving the number actually examined 1,198, as before stated. This year there has been in operation the system which was set on foot last year, of appointing visiting officers in each Union, to represent the Society, and to assist in organising the classes for adult teaching, and give aid in the formation of Local Boards, and information with respect to the Examinations. Thus visiting officers have been appointed for five Unions, as follows:—

Lancashire and Cheshire Union,	Mr. Thomas Lawton.
Metropolitan Association	Mr. H. H. Sales.
South Stafford Association	Mr. John Jones.
Worcestershire Union	Mr. F. Marcus.
Yorkshire Union	Mr. Barnett Blake.

The system, however, has been too short a time in operation to show any decided results in reference to the Examinations, though, without doubt, the labours of these gentlemen have tended to increase very materially the efficiency of the Institutions as educational establishments.

It will be remembered that in my last Report I mentioned the appointment by the Council of an Education Committee of the Society, which should include representatives from the various district unions, and whose duty it should be to

advise the Council with reference to the preparation of the Programme of Examinations, both elementary and final, and also to supervise the preparation of the papers for the elementary examinations, a work formerly performed by a body known as the Central Committee, with which the Society was only indirectly connected.

This modification in the arrangements, which, as I explained last year, was made principally with the view of avoiding the confusion that inevitably resulted from the anomalous position of the Society in the Central Committee, is believed to have worked satisfactorily. The number of candidates has considerably increased, although the Southern Counties Adult Education Society, which adopted this system last year, has this year not done so; moreover the number of centres of examination has been larger, showing that the interest in examinations of this character has been spread over a wider area.

Last year these examinations were held by 10 district unions or boards, at 104 centres; this year 16 district unions or boards have held them at 115 centres. In 1864 there were 1,795 candidates, of whom 877 obtained certificates. Of these, 435 were higher grade candidates, of whom 170 obtained certificates; 1,360 lower grade, of whom 707 obtained certificates; this year the whole number of candidates examined was 2,044, of whom 809 obtained certificates, the proportions being 594 higher grade, with 209 successful; and 1,450 lower grade, with 600 successful. The tabular statement shows that among the higher grade candidates were 55 females, 12 only obtaining certificates; and

among the lower grade were 214 females, with 97 successful.

It will be readily understood that these numbers, large as they are, most inadequately represent the amount of encouragement really afforded to the progress of Elementary Education by the various Local Boards and Institutions connected with the Society. A considerable number of them prefer adopting a scheme of elementary examinations of their own. Happily there are many highly-educated men on these boards who are perfectly capable of setting papers in such subjects as are usually included in the term elementary education, or of examining their candidates *vivâ voce*; and the reports of many of the Institutions show that periodical local examinations in those subjects which may be said to form the basis of all education are held in many localities with the best results.

In order to afford you more detailed information as to the state of many of the Institutions, I cannot do better than quote from the reports of our visiting officers:—

Mr. Barnett Blake reports as follows:—

There has been a continued favourable progress of the Mechanics' Institutes of Yorkshire, notwithstanding the occasional instances of depression, and a few cases of failure from exceptional causes. In the important feature of number of members, there are forty-two Institutes in which there has been a decrease of 823 members in the aggregate, but this is more than compensated by fifty-five other Institutes, showing an increase to the extent of 1,281 members. Of the larger Institutes, Leeds, Bradford, Halifax, Huddersfield, Wakefield, Darlington, Dewsbury, West Hartlepool, Scarborough, Bingley, and Keighley, show an increase considerably exceeding the slight diminution of numbers in a few others. It is, however, still more satisfactory to notice the much greater improvement in the number of class-pupils, which in fifty-nine Institutes amounts to above 18 per cent. over last year. Much of this improvement may fairly be attributed to the examinations of the Society of Arts which have been materially promoted by the Elementary Examinations. The advantages have been brought more prominently before the members of the smaller Institutes; success has been more apparently within reach, and consequently more highly appreciated, and in several instances it has led to the candidates who were induced to submit to the lower ordeal being encouraged to try for the higher certificates. Nor is the beneficial influence limited to that which appears in the number of successful candidates. At the presentation of Elementary Certificates and Prizes great interest is excited, and a stimulus given to many others to strive by mental application to achieve similar honours. I have been present on such occasions at Eston Mines, Hebden Bridge, Hunslet, Leeds, Ossett, Scarborough, Slaidburn, Stockton, and Thirsk, where the most lively interest was manifested, and further encouragement given by the offer of local prizes in addition to those given by the West Riding Educational Board. The Elementary Examinations have been held this year at twenty-one places in the Yorkshire Union where Local Boards were established for the purpose, and as seven of them were for the first time it is hoped that as every year they become better known the system will be still further extended. Of 117 candidates in the higher grade only forty were successful. Of the whole number 76 passed in Arithmetic, but 22 failed from insufficient

number of marks, and 10 failed in two additional subjects. Of 368 candidates in the lower grade there were 217 successful. Of the whole number 297 passed in arithmetic, and of these 19 failed from insufficient number of marks, and 50 failed in two additional subjects. As the greater number of the candidates are employed during the day, and have only the evening classes of the Institute by which the imperfect education of the day-school can be carried out, there is great difficulty in instructing them in history and geography sufficiently for the requirements of the Elementary Examinations. It is therefore by many considered desirable that, in the lower grade at least, it should be necessary only for the candidate to pass in one subject besides reading and arithmetic. There is, however, no doubt that the system is effecting much practical good by promoting a sound basis of instruction, and in many instances preparing candidates for the more advanced Examinations of the Society of Arts. The success of the system of Elementary Examinations may be still more evident when taking into account the large number of candidates, and bearing in mind that, with few exceptions, the larger Institutes of Yorkshire have not yet adopted it. Another good effect is the encouragement of the practice of plain needlework by young women of the working population, which is apparent not only in the increasing number of female candidates, but also in the increase of female members of Institutes, which amounts to nearly sixteen per cent. In 71 Institutes in the Yorkshire Union. This is an encouraging sign of progress, and the more valuable as it is the training of the wives of working men and the mothers of our future population. Some difficulty is experienced in carrying on the work of adult education, owing, in a few instances, to the want of competent teachers, but more often to the inefficiency of accommodation for classes. This, however, is endeavoured to be obviated by the erection of buildings, and several Institutes are now making exertions to raise funds for the purpose. At Bingley, and at Cottingley, a neighbouring village, very excellent buildings have lately been completed; whilst at Addingham, Almondbury, Calverley, Cleckheaton, Hartlepool, Leeds, Lockwood, Rothwell, Saltaire, and Shipley, funds are being raised with a fair prospect of success. In the reading-rooms of Institutes there is an increase in the number of newspapers and monthly publications, with a very slight falling-off in the number of weekly and quarterly publications, so that this department of the Institute is well maintained. In the libraries of 97 Institutes there has been an addition during the year of more than seven thousand volumes, which shows an increasing desire for literary pursuits, and is so far encouraging. Upon the whole, therefore, after making allowance for the few instances of failure, and the fluctuations to which a busy people are always liable, there is much reason to be satisfied with the condition and prospects of the Institutes of Yorkshire, and as the practical stimulus which is given to mental cultivation by the Society of Arts in its Annual Examinations becomes year by year better known, there is fair ground to expect a still increasing spread of education, and its accompanying blessings in a more civilised and moral population.

In reference to the Institutions in the Metropolitan District, Mr. Sales writes as follows:—

"The principal feature in the work of the Society of Arts, connected with Metropolitan Institutions during the past year, has been the establishment of evening classes on the basis of the City of London College and London Mechanics' Institution. These classes are held in school-rooms, as the Bromley Evening Classes; or, as in the case of the West London Youths' Institute, form part of an Institution. In either case the general principle is the same, viz., independent class instruction under duly qualified teachers. The extension of this system will produce an annual increase of candidates in the Society's examinations. In the institutions in the district, little direct educational work is carried on; but I believe that this is

owing to the prevalent system of establishing classes without regard to the requirements of the members, and placing them in the hands of unpaid teachers. The working-classes who frequent these Institutions are willing to pay for the instruction they require, but are keen enough, on the one hand to know what subjects are necessary for their individual advancement, and on the other to discern the failings of the system of voluntary tuition. As the evening class scheme becomes more generally adopted, greater progress will distinguish the operations of the Mechanics' Institutions, Mutual Improvement Societies, or by what other name they may be called. In addition to the reading-room, most Institutions include in their programme lectures, discussions, and choral societies, at which the attendance is generally satisfactory. At Greville-house Library and Reading-room a brass band has been organised, and is very popular among the members. Only one Working Men's Club is in union with the Society in London, but having, by request, attended many meetings of clubs, and explained the operations of the Society, I hope that during the ensuing autumn classes may be established in many clubs. In the Duck-lake Club, Westminster, a sound educational work is being carried on. Established for the lowest classes of the population, and frequented by them, it is not to be supposed that the attainments of the members are sufficient to bring them within the scope of the Final Examinations, nevertheless the instruction given produces perceptible and gratifying results."

Mr. Marcus, of the Worcestershire Union, reports—

That the Union at the present time embraces 28 Institutions and Twelve Night Schools. The members of the Institutes in Union and the attendants at the Night Schools have largely increased in numbers, and the schools are much better taught and managed. The results of the Elementary and other Examinations are also of a highly encouraging character, the numbers being largely in excess of previous years. In the Elementary Examinations by the Society of Arts there were for the Higher Grade 23 candidates, of whom 11 passed; for the Lower, 36 candidates, of whom 8 passed. This Union offers special encouragement to the candidate for these examinations by awarding three prizes (£2, £1 10s., and £1) to the best in the Higher Grade, and four prizes of 10s. each to the best in the Lower Grade. For the Final Examination of the Society of Arts there have been 19 candidates from the following Institutions:—Redditch Literary, Kidderminster Mechanics', Worcester Catholic, and Bromsgrove Literary. These numbers would have been largely increased were it not that several of the Institutes in Union, being also in alliance with the Staffordshire Adult Education Society, have elected to be examined under that Board. In addition to the Society of Arts' Examinations, the Worcestershire Union has had special examinations, and awarded prizes of its own.

Mr. Jones, of the South Staffordshire Association, says:—

The area covered by this Association has to a considerable extent been seriously unsettled during the past year by a succession of labour disputes, which have injuriously affected the position of many of the leading institutions of the district. At the same time several societies have extended their operations. The Willenhall Literary Institution have completed a new and commodious building, and have largely increased their member list. The class-work connected with the Institutes in Union has been, in the majority of instances, interrupted by the cause above mentioned. The Wolverhampton Working Men's College—a society which for seven years has successfully conducted a large number of classes—has not this season been so well attended, and is about to be suspended. On the other hand, the number of evening

schools has this season increased. I should here explain that the institutions in this district do not as a rule take up instruction in elementary subjects, as is the case in Lancashire and Yorkshire; this part of the work of adult education is carried on by evening schools. The Dudley Mechanics' Institute alone has an evening school as a part of its organisation, and it has this season been even more successful than in any former year. The number of Institutions in union with the Association is nearly thirty, but of these only a small proportion are connected with the Society of Arts. Several large institutions, lying just on the confines of the district, have applied for visits from me, and I have been able to stimulate them to prepare candidates for the Society of Arts Examination. On the whole I may say that, notwithstanding the temporary depression before mentioned, there has been much work done during the season, and there is every prospect that another winter will be much more satisfactory than the last.

Mr. Lawton, of the Lancashire and Cheshire Union, reports—

The working and progress of the Union of Lancashire and Cheshire Institutes during the past year will, to a considerable extent, be seen by reference to the following statistics:—

	Month ending May, 1864.	Month ending May 1865.
Number of Institutes in Union	80	118
Number of subscribers to the Union ..	41	113
Institutes in Union with the Society of Arts	19	29
Institutes with Day Schools under Government Inspection	9 per cent.	18 pr. ct.
Institutes with Day Schools not under Government Inspection	8 per cent.	13 pr. ct.
Institutes with Government Science Classes	18	23
Institutes employing paid teachers	45	63
Institutes with complete arrangements for preparing pupils for the Elementary Examinations	30	51
Number of Elementary Certificates awarded	69	172
Institutes with successful candidates at the Elementary Examinations	11	45

It may be observed that the principal objects contemplated by the Union are—(1) The establishment of suitable class operations. (2) The employment of properly qualified teachers. (3) The distribution of the Institutes into groups, with a view (a) of facilitating the working of the examination scheme and (b) of conducting classes for special subjects at the Central Institute on behalf of the district. (4) The awarding of supplementary prizes (a) by the Union and (b) by the several districts to the most successful candidates at the Examinations.

APPENDIX.

EXAMINERS' REMARKS.

The Examiners in the respective subjects make the following observations on the work done in this year's Final Examinations:—

Arithmetic.—As a whole, the papers this year are hardly equal to those of last year in power and accuracy. The writing out is clear and legible, and the figures are round and well formed.

Book keeping by Double Entry.—The average knowledge of the subject and expertness in work exhibited by the exercises in this department, as compared with those of former examinations, are well maintained, and I am well satisfied with the quality of the work generally. Some few papers are distinguished by great intelligence

and accuracy. The number of candidates continues to increase.

Algebra.—Whilst there have been several failures—rather more than one-fourth of the total number of candidates having fallen through—a good deal of talent and acquaintance with the subject has been evinced by a fair portion of those who have passed. Every question has met with a solution among the papers sent in, which is a favourable symptom, as one or two of them are of a kind to call forth the exercise of original thought. Altogether I regard the result of the examination as of an encouraging nature. In many instances the literary style of answering is good. In other cases, however, a more diligent study of the English language might be recommended with advantage to some of the candidates. The word “ternary” appears to have been a stumbling-block to some, it having been variously interpreted as referring to the numbers 2, 5, and 7.

Geometry.—The general character of the papers is good. Several candidates have evinced aptitude in solving problems. Many have shown that they appreciate closeness of logical sequence, and none failed to exhibit some benefit gained by their study of the subject.

Mensuration.—It may be observed that none of the candidates are in the first class, and that there are too many in and below the third. This I attribute to the want of due attention to the elements of the subject. In the arithmetical part their work is satisfactory, but in the geometrical part it is not.

Trigonometry.—The answers to the questions were very well worked out, and although none of the candidates obtained sufficient marks to be placed in the first class, those who have second-class certificates did not fail for want of ability. All the important and more difficult questions were answered by one or other of the candidates.

Conic Sections.—Only one candidate has answered the questions in the Conic Sections and Algebraical Geometry paper. Although the answers are not as good as heretofore, yet the subject deserves encouragement, for the disciplinary value of it is very great, and I cannot recommend the Council to discontinue it.

Navigation and Nautical Astronomy.—The number of candidates in this subject is still very small. There is an improvement in the style of working the problems, and two first-class certificates have been awarded.

Astronomy.—It is strange that a single candidate only furnished any answers to the several questions. Year by year I have been urging increased attention to those parts of mathematics on which astronomy rests, and upon their practical application. In previous years I have totally failed in obtaining one satisfactory answer to any question on either the theory or the practice of interpolations. Last year a very satisfactory advance was shown in the application of spherical trigonometry, and in the practical reduction of observations as far as required. This year this is almost totally wanting, and the questions answered or attempted to be answered, were those rather upon the literature of astronomy than upon astronomy either theoretical or practical. I am disappointed. It is clear that the paper set, although by no means difficult, has been so considered. I suppose next year the examination paper must be more elementary. This is to be regretted. In the answers some knowledge of the application of algebra and trigonometry is shown, but to no great extent.

Principles of Mechanics.—Pleased as I am with the evidences of considerable knowledge on the part of the majority of the candidates, yet my pleasure is mixed with some regret in seeing a want of clearness and perspicuity, which spoils the effect of the results, and renders it a difficult task to assign fairly the marks due to them. I have never been obliged to send you a qualified report before, but on this occasion I think that a word of cau-

tion to the candidates as to more earnest effort to secure method, well-digested arrangement and neatness of their papers will be for their good. I am glad to be able to mention one exception to the defect which marks the generality of this year's papers.

Practical Mechanics.—I have been unable to award any certificates of the first or second class. I believe that this is the first occasion upon which so unfavourable a result has occurred, and it has been very apparent to me that the candidates have not entered with sufficient assiduity upon the course of reading pointed out for their guidance.

Electricity and Magnetism.—The examiner has much pleasure in reporting that one of the two most useful practical applications of this subject, namely, electrotelegraphy, appears this year to have received more attention than heretofore. The other not less useful application to the mariner's compass, its construction, deviations, and the most practicable methods of correcting the errors therein arising, does not yet appear to command the attention of advanced students to the extent the subject is entitled to, considering the present and increasing importance of iron in marine architecture.

Light and Heat.—The candidates have all shown considerable knowledge of the properties of light and heat, which form important portions of Natural Philosophy. They have all, however, shown the need of more earnestness in answering examination questions, so as to enable them to make the best use of their acquired knowledge during examinations, by answering each question completely and yet in a condensed, distinct, and accurate manner, giving also the figures correctly where required.

Chemistry.—There are distinct evidences in the papers that candidates pay more attention to analytical chemistry than was the case some years ago. But still there is considerable room for improvement in that direction. I believe that many teachers of chemistry are hardly aware how easy it is to give practical instruction in elementary qualitative analysis to students without great expenditure of time or money. Every course of instruction in chemistry might include practical exercises of that kind.

Mining and Metallurgy.—The observations of last year are equally applicable to this. None of the papers exhibit a degree of excellence worthy of special remark.

Botany.—Of the twelve candidates this year, three have not complied with the required conditions as to the number of questions to be answered in each section. The only candidate passed in the first-class left five questions unanswered, but the answers given indicate a well-grounded acquaintance with the subject. The papers of the second class are of tolerable promise, and improved by another year's experience would probably rank higher. All candidates would do well to handle living plants more frequently, dissecting and describing them as they go on in accordance with the examples given in the works recommended to them as text-books.

Animal Physiology.—The results of the examination this year show that, out of eighty-four candidates, four are in the first class, twelve in the second, eighteen in the third, and fifty are not placed. Since both teachers and pupils and self-taught students may be supposed to have learnt, by the issue of previous examinations, the real merit, in its several degrees, can alone obtain the several orders of certificates, it seems, at first sight, disheartening that the results are not more satisfactory. Of the fifty candidates “not passed,” thirty-three have obtained only 20 per cent., or less, of the full number of marks; and I have no hesitation in describing these as immature students, even of their own language, purely offering themselves for an examination in so special a subject as Physiology. The first paper in the first class is admirable, a few slips only depriving it of the

all number of marks. There are a few papers in classes 3, and 0, which fail to take higher places from deficient quality of answers, the quality being good of what they contain. To justify my strictures on the majority of thirty-three of the fifty unpassed papers, I append a few samples of the sort of delinquency which I maintain against the authors of them for being candidates in an advanced science:—

I.

Errors in scientific terms which may be more or less excused, perhaps:—

Membrum tympanum	} for membrana tympani
Membrana tympani.....	
Cancellæ.....	" cancelli.
Aguor sanguinus capillaries	} liq. Sanguinis capillaries.
Lammils	} " mammals.
Laminiles	
gelatinous	" gelatinous.
carbonaceous	" carbonaceous.
sacchrine	} " saccharine.
sacchrine	
Nucleus	" nucleus.

II.

Errors in English, unpardonable:—

hues	for oozes.
hair-like vessels	" hair-like vessels.
[ake] pains	" pains.
not	" a knot.
owl [air]	" foul.
lear	" hair.
respir	" respire.
different	" different.
suffocation	" suffocation.
asleep	" asleep.
ear	" ear.
air	" air.
has	" has.
bile	" bile.
incredible	" incredible.
odours	" odours.
too	" too.
secretes	" secretes.
together	" together.

The use of two I's for one is constant, as in "ventillation," "controll," &c. Such phrases as these occur—"is for to make," "greatest of nicety," "inodorous smells" [used twice in the same answer, so the incongruity is not accidental, but in the writer's mind], the blood is "also contaminated" by saline constituents which are natural to it—and so on.

III.

Errors of a special kind and absurd:—

1. "Pancreas" means "sweet," means "sweet-bread;" is so-called, i.e., pancreas, because it is "sweet," because it is "acid;" it lies "behind the back;" it is a "bag;" it is "above the diaphragm." 2. Bone is formed of "mucous" matter outside, and of "nervous" matter in, the latter being partly grey and partly white; it is made of "cells" and "sacs." 3. Bone "consists of long layers of cartilage arranged in a very nice manner;" "it has a pleasing structure." 4. The red blood corpuscles each contain a gland and a duct," but "it requires a great power of the microscope to find them." 5. The "external auditory meatus," being confounded with the "alimentary canal," by two candidates, is described as "twenty feet long, one and a half inch wide, and going zigzag through the abdomen, &c." 6. The "Eustachian tube" assists in breathing;" "it exists," the same writer adds, "in man, ourang-outang, and all kinds of monkeys;" "it carries away wax;" "it carries away mucus and excess of air after it has been used for making vibrations;" "it prevents choking;" it is "connected with the la-

byrith, and only exists in those classes of animals who have a keen sense of hearing, as the deer, man, &c.;" it "carries away effete or superfluous matter into the nasal cavity." 7. Reflex movements are such as the "secretion of gastric juice;" by sensori-motor movements "we act as we think proper." As two final examples I transcribe the following literally:—"The osseous tissues present a very pleasing structure under the microscope, the majority of them being of a circular-like shape, with a kind of a nucleus in the centre, and are so adapted to fit closely together and form a compact mass, and are so small that they are easily carried along with the blood to that portion of the bone that needs nutrition." 2. In answer to a question on the uses of the blood and of its several parts, a candidate's sole reply is this—"The blood is said to be the life of the body, for there is no part of our body, if an incision be made in, the least whatever, some portion will come out. It also helps to nourish and build up this goodly frame of ours. Its constituents are, in a pure state, salts, albumen, fibrin, red and white corpuscles, these may be found in coagulated clot." The inaccuracies, the confusion of thought and expression, and the bad grammar, punctuation, and orthography, illustrated by the above examples of errors, constituted about one-third of what a strict scrutiny would reveal. Unless dealt with firmly such defects may increase. Nay, in my opinion, they require exposure, and public notice of some kind or other. At all events, advice should be given to future candidates or their teachers, as, indeed, I gave last year. If a strict hand be not held over them, the examinations of the Society of Arts in the subject of "Animal Physiology" will do not only no good, but a large amount of evil.

Domestic Economy.—The answers sent in this year on this subject show a gradual improvement over past years, and are better than in any previous examination which I have had, some of the answers showing a knowledge of the nature and composition of food, &c., and that the writers of them have profited from such papers as those of Dr. Lyon Playfair, in *Good Words*, and altogether making one feel that their knowledge may be useful to them in every-day life.

Geography.—I am better satisfied, on the whole, with this year's papers than with those of any former occasion. A large number of them reach a fair, and several a very high, degree of merit. There are, indeed, several failures; but, taken altogether, the answers give evidence of more preparation and of study directed to a definite purpose, than I have hitherto observed. This is an advance in the right direction. In geography, as in other subjects, diligent and methodical study, directed by progressive stages towards a definite object, can alone lead to success. The first-class papers of this year do very great credit to the writers.

English History.—The answers on this subject are, on the average, better than those of last year; though a few are so bad that it is difficult to understand how their authors can have been advised to offer themselves for examination on this subject. Those who are placed in the first class have laid a good foundation for future reading; but those in the second are generally deficient in accuracy as well as in quantity. Perhaps the period proposed as the subject for examination is too long. If by shortening it more accurate knowledge could be secured, the change would certainly be for the better. With regard to the form of the answers, there is a great improvement this year; and, with a view to maintaining this advance, it may be worth while to repeat the suggestion made last year—that candidates should practice themselves in answering questions on papers for their tutors from time to time.

English Literature.—The papers which I have now examined are certainly not less satisfactory than those of any previous year. There are but very few of them in which the candidates have not proved their sound ac-

quaintance with the text of the books in which they have been examined. A good proportion of the answers are well expressed, and show thoughtfulness and judgment. But two or three of the candidates have wasted their time in making imperfect, though tedious, grammatical analyses of the passages contained in the questions. As I have met with the same in some former examinations, I think it best to give a caution on the subject. It should be understood that no marks can be given for anything beyond an answer to the examiner's questions.

Logic and Mental Science.—Nearly all the candidates show very fair preparation in the subject of logic, and a few more than a popular acquaintance with it. The papers on mental and moral philosophy are not generally so good, and mostly evince a hasty preparation of the subjects. Some of the candidates, however, show a very fair acquaintance with one or even two of the prescribed text-books.

Latin and Roman History.—The work has a little fallen off both in quantity and quality.

French.—On the whole this year's papers are very satisfactory. It is true that I can only recommend four candidates for a first-class certificate, and that for papers which only just reach the standard. Nor are the second-class certificates numerous either; but I am able to award no less than fifty-one third-class certificates, which raises the total number of successful candidates to about three-fourths of the whole number, a proportion considerably larger than on any previous occasion, whilst the standard this year is certainly not lower. The chief cause of this result is the fact that the candidates have mostly confined their attention this year to one section of the examination paper, instead of attempting to give unconnected fragments of the different sections, as was too much the case previously. Altogether the candidates seem to have gone more methodically to work, which is in itself a great progress.

German.—In comparing this year's papers with those of last year, I am happy to find that in every section they are distinguished by greater ability and bear the marks of closer application. Not one candidate had to be rejected. Only six out of nineteen did not write the essay; some of those, however, who have done so, sometimes deviate from the point in question. A stricter keeping in view of the subject to be handled, and a more logical method of arranging the matter, ought in future to be aimed at. The questions on Grammar are answered with greater precision than last year, and the majority of the translations from German into English are very good. The gainer of the highest number of marks has mastered all the four pieces selected for translation, and left hardly any part of the examination paper untried.

Italian.—The papers, with one single exception, are highly satisfactory. The candidates have shown that their knowledge of Italian exceeds the average standard usually attained by many who yet are supposed to have mastered a foreign language. One paper evinces much readiness, if not style, in translating into Italian; and all show careful grammatical studies, and a fair acquaintance with the peculiar idioms.

Spanish.—Most of the candidates have tried for a higher certificate than their knowledge of Spanish seems to warrant, and a few only have complied with the requirements. This mistake has damaged the result of the examination of some who, in all probability, would have been more successful had they tried for a lower class certificate.

Free-hand Drawing.—Candidates for examination were requested to bring any drawings they had made during the last twelve months as proofs of their abilities; this gave each candidate an opportunity of showing what he had learnt, and what his taste was, if he had any peculiar talent. There were fifty-six candidates who sent in

drawings of the following subjects:—Two, flowers; three original designs for manufactures; seven, human figures, or portions of eight, landscapes; thirty-one, copies of scrolls and drawings of flattened leaves and flowers. This anal pretty well what is being done for art-education out the country.

Geometrical Drawing.—Since the general national examination in Practical Geometry must be held from year to year, it might be expected to be better. This, I regret to see, is not the case,—the proportion of failures to the whole number is greater on the former occasions. It is well perhaps to point out the apparent causes of these failures in the hope of putting future candidates more on their guard against them. They are—1st. A neglect of the conditions of the examination, either arising from carelessness in reading or from misconception of their import; 2. Not heeding the repeated injunction not to attempt more than the prescribed time allows of being carefully and thoroughly accomplished; 3. A want of knowledge of the principles of solid or co-ordinate geometry, causing a great waste of time by compelling the candidate to adopt complicated and circuitous constructions instead of the simple ones based on sound elementary knowledge. It is but fair to the successful candidates to state that their work is highly creditable, as regards the neatness and accuracy of their drawing.

Music.—This year's are certainly, on the whole, the best papers I have yet had. Of the few candidates who have not passed, the failure is attributable (on some occasions) to their having attempted the hardest counterpoint questions, with insufficient preparation, or to the neglect of those questions which they might have answered correctly. The papers—nearly half of those worked—are very

TABLE III.

This table shows the ages of the 1,369 candidates from whom return papers were received. Of these, 1,000 underwent the final examination.

The report of the discussion will appear in next week's *Journal*.

Fine Arts.

MONUMENT TO EUGENE DELACROIX.—A monumental tomb has just been raised over the remains of the painter Delacroix, in the cemetery of Père la Chaise. It is executed, according to the desire of the deceased, in the severest style of Greek art, and consists of a simple parallelogram of Volvic stone, placed upon a granite base—in fact, a copy of the "Tomb of Scipio"—and bearing no other inscription than the name of the deceased. A number of artists and friends of the late painter attended the ceremony; and discourses were pronounced by M. Rivet and by M. Berryer, who spoke impromptu at the urgent request of those assembled.

MONUMENT TO PEDRO IV. AT LISBON.—Two French artists, M. Daviond and M. Robert, have obtained the first prize in this competition; a native artist obtained the second, another French sculptor the third, and the fourth and fifth were awarded to Italians. The design is new, and deserves a few words of description. The monument will consist of four parts—a basement of granite, a pedestal, a column, and a statue. At the angles of the square basement are four seated figures, representing Prudence, Justice, Force, and Temperance; the effect of these is to connect the whole design, and lead the eye naturally from the base to the summit. On the walls of the basement are sculptured the arms of the

twenty principal towns in the kingdom, indicating the popular unanimity of the nation in the work. On the pedestal are inscribed the facts which gave rise to the monument. The column is decorated with four figures of Fame, in bas relief, on its lower portion, and these figures are connected together by garlands. The capital of the column is decorated with the cypher and arms of the king, in the midst of palm branches and symbolic flowers. The figure of Don Pedro IV. is dressed in a general's uniform; the right hand holds the constitution which he inaugurated, while the left rests on the hilt of the sword. This statue is to be ten feet high, cast in bronze, and gilt by the electro-galvanic process. The entire monument will be nearly one hundred and forty feet high.

EXHIBITION OF CARICATURES.—The whole of Europe and France in particular is just now full of exhibitions—agricultural, industrial, artistic, and miscellaneous. One of a new kind is talked of in Paris at the present moment—an Exhibition of Caricatures. There is little doubt that such a collection might be made extremely interesting, but at the same time there would be some difficulty in knowing what to admit and what to exclude. Not only would the political question raise some difficulties, but many of the productions which a hundred years since were considered only grotesque could not now certainly be exhibited in public. Such an exhibition, moreover, could not well be made international; few nations would like to show how they sketched others in past times, or to see how the caricaturists of other nations treated them.

Commerce.

PRESERVATION OF SHIPS.—A communication has been made by Lieutenant A. Mariot, of the French navy, relative to the means employed by the Cochinchinese to protect the hulls of vessels from the attacks of the auger-worm and other mischievous creatures. M. Mariot declares that the Chinese and Annamites know how to protect their vessels effectually, and at a very small cost, and a long residence in the two countries as a naval officer gives weight to his evidence. He was struck with the extreme antiquity in appearance of many of the native vessels, and found on inquiry that they were quite as old as they looked, and that in some cases they had been bequeathed from father to son until their origin was entirely forgotten. The timber of these vessels being the same as that employed in India for the same purpose, and the waters of Cochinchina teeming with destructive creatures, it was evident that the durability of the vessels arose from some special precaution. The means employed are, according to Lieut. Mariot, a mixture of a resinous oil with a resin, applied hot to the wood; both the substances being special products of the lands on the banks of the river Meikon, the trees which yield them having heart-shaped leaves, strong roots, and throwing out suckers. The tree which yields the oil is called by the Annamites caydan, literally oil-tree, and often attains a height of more than two hundred feet; it will furnish from three to five pints of oil per week. Boats made of the wood of this tree are said never to be attacked by the auger-worm. The tree which yields the resin is described as being somewhat similar to the former. M. Mariot, when in command of the *Amphitrite* lorch, under Admiral Charner, employed the native mixture on a boat which had been attacked by the mollusks, and at the end of a year it was perfectly free from any fresh attacks.

GUANO IN FRANCE.—A large deposit of guano, the produce of bats, has been discovered in a natural cave, belonging to the Commander de Beaufond, eight miles distant from Vesoul, in the department of the Haute-Saône. The deposit is estimated at about eight hundred cubic metres. This discovery recalls another which was made many years ago by Mr. George Windsor Earl, now magistrate at Penang, and published in London about the year 1854. This gentleman, in his geographical and ethno-

logical researches, discovered that vast caves in the innumerable islands of the Indian Archipelago were filled with the *detritus* of bats, which are of enormous size in those latitudes, and have existed there by myriads, almost undisturbed, for ages. Mr. Earl says that the amount of guano in those islands is incalculable. A French chemist has analysed the guano of Vesoul, and considers it valuable as manure, a fact which helps to validate Mr. Earl's discovery, as both deposits are produced by the same creatures.

THE EXHIBITION AT BOMBAY.—The promoters of the proposed Great Exhibition at Bombay are losing no time in pushing forward the scheme. Already a Building Committee has been formed who will superintend all the necessary arrangements. Another has been appointed for India, one for China and Japan, one for Australia and Cape, one for Persia and Egypt, one for Europe (to correspond with the London Commission), and one for America (corresponding with the New York Commission). A District Committee is formed for regulating the arrangement of all the articles in the building, as Government has been applied to in order to form all committees throughout India.

Colonies.

INTERCOLONIAL CUSTOMS.—It appears that Victoria is going in the direction of protection, while South Australia, which is contending with it for the trade of Western Rarima, is being urged by others to go to the opposite extreme of an immediate abolition of the Custom-house. A proposal to that effect was brought forward in the Chamber of Commerce at Adelaide, but it does not appear to have excited much attention. Only 30 attended and only 19 voted. The result was that 14 persons expressed themselves in favour of an immediate abolition of the Custom-house. It was argued that a moderate increase of direct taxes would enable the revenue to dispense with the Custom-house, but how it was to be collected or what would cost was not gone into. The special reason which makes the policy of South Australia interesting to New South Wales is, that, if it were to adopt the system of open ports, it would either compel New South Wales to do the same or put it to great expense to guard against smuggling. If spirits were admitted duty free into South Australia, how are they to be kept from the back territories of New South Wales? It would pay to cart the contraband commodities for long distances towards Sydney, perhaps into Sydney itself. A preventive service on the River Murray would be very inconvenient, and perhaps not effective, although New South Wales has only to guard against goods that have paid full duties. How much more troublesome to guard against the introduction of goods that have paid no duties at all. South Australia is, perhaps, in a better position to be able to dispense with customs dues than any of its neighbours.

Obituary.

SIR JOSEPH PAXTON, late M.P. for Coventry, died on Thursday, the 8th inst., at his house, Rockhills, Sydenham. He was the son of poor parents, and was born at Milton Bryant, near Woburn, Beds, in 1808. Having while very young to seek his own livelihood, he became a gardener, and in that capacity obtained a situation to work in the gardens of Sion House. He rose to the post of foreman, and was gradually promoted by the Duke of Devonshire to the position of director of the garden at Chatsworth, and afterwards to that of manager of the Derbyshire estates belonging to the duke. He remodelled the whole of the gardens, and the many magnificent works now standing there were carried out under his direction. Amongst them was the great conservatory, a glass and iron structure, 300 feet long, which he made

a model for the great building in Hyde-park, and then the present Crystal Palace at Sydenham. His design for the erection of a building to be constructed of glass and iron, for the Great Exhibition of 1851, was accepted by the Royal Commissioners, after 253 plans had been rejected. For his public service on this occasion he was knighted. In 1853 he commenced the building of the Crystal Palace, which was completed and opened to the public in June, 1854. In the same year Sir Joseph Paxton held himself as a representative for Coventry, in place of his friend Mr. Gresham. He was elected without opposition, and retained his seat till a few weeks ago. Shortly after his election he tendered to the Government a practical suggestion to send out a corps of navvies to perform military work at the siege of Sebastopol, then going forward. His proposal was accepted, and he was entrusted with the organisation of the Army Works Corps—a duty which he discharged with great credit. In politics he was a Liberal, and a consistent supporter of Lord Palmerston's administration. He followed the profession of an architect and civil engineer from the time when he constructed the great glass building in Hyde-park; but he did not relinquish his position at Chatsworth. He was happy in the constant esteem of the late Duke of Devonshire, who, some time before his own death, handed to him a life-interest for £20,000, upon which he charged himself to pay premiums for Sir Joseph's benefit. Sir Joseph Paxton was an industrious writer on horticulture, and connected with several literary enterprises. He was a Fellow of the Horticultural Society, 1826; of the Linnean, 1833; and in 1844 he was made, by the Emperor of Russia, a Knight of the Order of St. Vladimir. The Silver Medal of the Society of Arts was presented to him in 1840, for a communication respecting his invention of a machine for the purpose of making sash bars, the account of which is given at page 87, vol. 53, of the *Society's Transactions*. He was elected a member in 1850, and was a Vice-President at the time of his death.

Notes.

THE CO-OPERATIVE PRINCIPLE IN FRANCE. — The writer states that the chief instances of application of the principles of co-operation in the building trades are to be found in France. Somewhere about twenty-three years ago, M. Leclaire, the house painter, whose experiments in connection with painters' work have often been mentioned by us, described in a pamphlet the system adopted in his establishment, and gave the reasons that led him to establish it. At present the concern is a partnership, consisting of M. Leclaire himself, M. Defournaux, and the Société de Secours Mutuels, of which all persons in the establishment are members. In the first year the men who worked 300 days made each 300 francs (£12) the profit, or beyond the wages, which were 4 francs a year. Improvement in the habits and demeanour of the workmen was immediately manifest. M. Chevalier, in 1848, stated, on the authority of M. Leclaire, "that the increased zeal of the workpeople continued to be a full compensation to him, even in a pecuniary sense, for the share of profit which he renounced in their favour;" and in 1857, M. Villiaumé gave similar testimony. The passing of the Limited Liability Act first made similar associations possible in this country. Of successful associations of operatives alone there are in Paris upwards of one hundred. The chief of these associations is that of the maçons. Its amount of business done from 1852 to 1858, both years inclusive, has increased from 45,530*fr.* the former year to 1,231,461*fr.* in the latter, and its profits from 1,000*fr.* to 130,000*fr.* It lately paid 56 per cent. the dividend of the year on the capital. M. Villiaumé remarks that intemperance greatly decreases amongst the members of the different associations, as well as every-thing of the nature of coarseness and rudeness. Mr. Mill,

and all who have studied the subject, expect a great increase in the productiveness of industry from the advance of the co-operative movement.

Correspondence.

ON THE WEAR AND TEAR OF STEAM BOILERS.—SIR,—Anybody who chooses to read my two "double-barrelled" letters—each barrel of which seems to be regarded by Mr. Clark as a modern form of the horns of a dilemma—will find convincing proof that Mr. Clark has again been drawing upon his memory for his discoveries, and upon his imagination for his claims. The ostrich-like style of defence that consists in ignoring statement and argument alike, and the lady's reasoning of continued iteration, can be of no avail to my respected neighbour with those who will give themselves the trouble of reading my "double-barrelled" epistles, as they are termed by Mr. Clark. Just, however, as even a Colt's revolver is of no use against the hide of a rhinoceros, so will no "double-barrelled" epistle—perhaps not even a round robin—be of any effect against Mr. Clark's own tough cuticle. I must confess, however, that this is quite indifferent to myself. Mr. Clark's little weaknesses on the subject of steam boilers are pretty generally known by this time. "That's my thunder—that my explanation of explosions," are perennial cries with the sage of the Adelphi, as of yore with Dennis the actor. Like another great man, he delights in fighting for ideas—and for ideas which he may annex, but certainly has never discovered. Mr. Clark's practised and boa-constrictor-like powers of literary deglutition are indeed fully recognised. The publicity, in fact, of the existence of Mr. Clark's little self-delusions on this score forms my protection. This will probably be the case even with that majority of your readers who do not care the value of an old bolt for either Mr. Clark or myself, therefore I must say that, for my own part, I do not so much regret his assertion that I have borrowed ideas from him without acknowledgment as my implied belief in the unscientific and mistaken twaddle which Mr. Clark dignifies with the title of explanations of the pitting and furrowing of steam boilers. In the one sentence by which Mr. Clark attempts to explain pitting, he is seemingly unaware of the existence of such an action as chemical affinity; and in his "explanation" of furrowing he has never dreamt of that action of internal fluid pressure which tends to form a perfect cylinder. As regards pitting, all Mr. Clark's explanation is contained in one single sentence—a sentence, by the way, which he introduces with the remark "that we are aware that electrical and galvanic action are adduced in 'explanation'" (of furrowing and pitting). "But these words," continues Mr. Clark, "have two meanings—they mean electricity and galvanism, and they mean ignorance and mystery." We see here, as plainly as anything written can be plain, that Mr. Clark expressly repudiates galvanism as accounting for pitting. We now come to that single pregnant sentence which, like a Delphic oracle, contained everything yet in the womb of the future. Instead of "ignorantly" having recourse to galvanism, Mr. Clark says—"The pitting of the metal is readily explained by the presence of chemical agents in solution in the water, and the known inequality of substance of iron plates and bars, in consequence of which the metal is gradually but unequally separated and dissolved, and probably a weak galvanic circuit may be established between the iron shell and the brass tubes, accelerating the process of dissolution." Only in that portion of the sentence which I have italicised is there to be found any attempt at explaining the irregular pock marks of pitted plates; the latter portion is, as I have shown, copied from Professor Tyndall, and could, in any case, only account for an equally spread corrosion. What Mr. Clark says, neither more nor less, is, that some

spots of the metal are softer than others—an isolated physical fact that could not, *per se*, explain why any softer or harder spot should be sooner dissolved than any other. He simply says, that some portions are easier dissolved than others, from being softer than others. In fact, it amounts to no explanation at all. Years ago I have heard a stoker explain pitting in this way; and Mr. Clark has simply clothed it in a Johnsonian sentence. In a similar mode Mr. Clark talks of "the indirectness of the strain of the steam pressure" at the joints, which is quite a different explanation from that which ascribes furrowing to the mechanical tendency to produce a correct circle, and to the furtherance of corrosion in the absence of that protecting coating of incrustation which is continually being broken off by the mechanical action. I defy Mr. Clark to show that either of these points, amongst others, have been even alluded to by himself. As to the explanations I give of the deterioration of stay-bolts, the best joke is that they are quite distinct from that of Mr. Griggs, published five years before its assimilation by Mr. Clark. Rightly or wrongly, I import novel elements into the matter. I can only suppose that Mr. Clark has not done me the honour to read what I have written, and that, misled by a strange self-delusion of which he has given previous proofs, he has claimed the explanations from the mere fact of their dealing with steam boilers.—I am, &c., F. A. PAGET.

18, Adam-street, Adelphi, W.O.

[This correspondence must end here.—Ed.]

ATMOSPHERIC RAILWAYS.—SIR,—The atmospheric railway proposed to be laid down along the banks of the Thames is neither more nor less than the invention of the late Mr. Vallance, the well-known banker at Brighton. Thirty or forty years ago that gentleman laid down an experimental vacuum railway of one quarter of a mile in length, of the full size, and carried passengers up and down for some time very successfully. The only difference in detail between the present plan and the former is, that the exhaustion is intended to be applied at one end only, and pressure for the return trip, a variation that will not ultimately be found to answer, the object in the present plan being evidently to avoid the expense of an exhaustor at each end. In practice, however, there is a very great difference between exhaustion and compression. In the former case the action seems to be instantaneous, while in the latter the effect is unaccountably retarded, owing perhaps to the elasticity of the atmosphere combined with the friction in the tube. Under the compressed system it has been found that if the pipe of communication be sufficiently long, the most powerful forge blast will not blow out a lighted rushlight placed at the further end.—I am, &c., HENRY REVELEY.

GRANTS OF PROVISIONAL PROTECTION.

Buttons, manufacture of—1110—T. Greaves and J. S. Wright.
Carpet, manufacture of—1499—W. Edwards.
Casting, apparatus for making cores for—1429—D. Law & J. Bennett.

Chimneys, preventing downward draft in—1471—E. Myers and J. Stoddard.
Circular saws—1475—W. T. Hamilton.
Coke, ovens for the manufacture of—1438—J. Giers.
Cotton, hydraulic presses for packing—1288—E. T. Bellhouse and V. J. Dornling.
Cotton, rollers used in preparing—1439—W. E. Newton.
Drain pipes, apparatus for laying—1396—W. Eddington.
Fire-arms—1438—E. Paton.
Fire-arms, breech-loading—1461—T. Bissell.
Fire-arms, breech-loading—1356—R. A. Brooman.
Furnaces—1451—M. Cohen.
Furnaces—1469—P. Young.
Furniture, construction of vans for transporting—1485—F. Hamlin.
Gas burner—1437—G. Bray.
Hoops, &c., manufacture of—1426—J. Ramsbottom.
Iron, manufacture of—1310—J. Bennett.
Knitting machines—1446—W. Clark.
Lamps—1423—C. E. Moller.
Lathes, reets for ornamental turning—1441—T. H. Heblia.
Lime, manufacture of—1467—P. A. le C. de Fontaine-mores.
Locks, keys of—1486—S. Grafton.
Locks—1487—J. Calvert.
Locking screws—1473—F. A. Paget.
Machines, reaping and mowing—1371—W. Manwaring.
Machines, rotative—1447—J. A. Heinrich.
Oils, purifying animal and vegetable—1453—S. Sequelina.
Pendants, sliding gas—1381—G. H. Brookes.
Railway trains, communication between passengers and guard—1493—I. Rogers.
Sail cloth, printing upon—1906—J. Isherwood.
Screw gills—1419—T. Bealand.
Ships' bottoms, paints applicable to—1489—T. Spenner.
Ships, apparatus for steering—1394—J. Martin.
Ships, machine for loading and discharging cargoes from—1440—E. Elliott and R. P. Clark.
Spherical form, machinery for turning bodies of a—1450—T. Bess.
Spinning machinery—1483—M. Melsel.
Steam boilers, composition for preventing incrustation of—1394—E. Hewitt.
Steam boilers, furnaces of—1372—T. Molden, J. Newsome, and A. Akeroyd.
Steam hammers—1491—P. Pilkington.
Telegraphic supports—1390—G. and A. Varley.
Tires, cast-steel railway—1455—J. M. Rowan.
Trimming, manufacture of—720—J. P. Booth.
Tubes, apparatus for cleaning the interior of—1479—J. Hare.
Weaving, looms for—1427—D. Welsh.
Whales, rocket guns for the capture of—560—T. W. Roys and G. A. Lillendahl.
Writings, &c., producing copies of—1457—R. A. Brooman.

INVENTION WITH COMPLETE SPECIFICATION FILED.

FINANCIAL STATEMENT.

The foregoing statement is published in this week's *Journal*, in accordance with Sec. 42 of the Society's Bye-laws, which provides that, at the Annual Meeting, the Council shall render to the Society a full account of their proceedings, and of the receipts, payments, and expenditure during the past year; and a copy of such statement shall be published in the *Journal* of the Society, on the Friday before such General Meeting.

ANNUAL GENERAL MEETING.

The One Hundred and Eleventh Annual General Meeting, for the purpose of receiving the Council's Report and the Treasurers' Statement of Receipts, Payments, and Expenditure during the past year, and also for the Election of Officers, will be held, in accordance with the Bye-Laws, on Wednesday, the 28th of June, at 4 o'clock.

The Council hereby convene a Special General Meeting of the Members of the Society to ballot for members, such meeting to take place at the close of the Annual General Meeting.

By order,

P. LE NEVE FOSTER,
Secretary.

Society's House, Adelphi, June 21st, 1865.

PRIZES FOR ART-WORKMANSHIP.

The Council have much pleasure in publishing the following letter:—

17th June, 1865.

DEAR SIR,—Referring to your letter of the 10th of January last, soliciting the co-operation of the Worshipful Company of Plasterers, London, in offering prizes for Art-Workmanship, I have now the pleasure to inform you that the Plasterers' Company have resolved to offer through the Society of Arts one prize of £10 and a second of £5 for modelling.

I send on the other side the particulars of the subject selected, and also the conditions, subject to which the prizes are offered, and I should feel much obliged if you would kindly make the same known as extensively as possible.

I am, dear Sir, yours faithfully,

H. MOTT.

P. Le Neve Foster, Esq., Secretary to the
Society of Arts, Adelphi.

The Worshipful Company of Plasterers, London, offer (subject to the general conditions of the Society of Arts) a prize of £10 for the best floriated bracket or truss in the Italian Renaissance style—dimensions, 14 inches on the beam, 12 inches on the wall, and 8 inches on the face—to be designed and modelled by the competitor, or the designer and modeller may co-operate in the production, when £5 will be awarded to each.

Five pounds will be given for the next best model, or £2 10s. each to designer and modeller.

Artizans' apprentices and students may compete for these prizes, but not master tradesmen, Masters in Schools of Art, or those training for Masters in the Central School of the Department of Art.

To be delivered at the Society of Arts by the 14th December, 1865.

Proceedings of the Society.

FOURTEENTH ANNUAL CONFERENCE.

The Fourteenth Annual Conference of the Representatives of the Institutions in Union, and the Local Educational Boards, with the Council of the Society, was held at the Society's House on Wednesday, the 14th inst, at 12 o'clock, noon. WILLIAM HAWES, Esq., F.G.S. Chairman of the Council, presided.

At the conclusion of the Secretary's Report to the Council, read to the Conference, and published in the last number of this *Journal* (p. 506), the Chairman laid before the Conference the proposed Programme of the Examinations for 1866, and called attention to the following subjects proposed for the consideration of the Conference:—

1. The establishment of organising teachers among the Institutes, on the plan adopted in the East London Union.
2. Is any modification of the present scheme of Elementary Examinations, by rendering it more adapted to the capacities of class pupils in Mechanics' Institutes, desirable?
3. The advantages of local prizes to successful candidates, at the Society of Arts Examinations, as a stimulus to local competition.
4. Whether any special inducements can be held out to lead soldiers to avail themselves of the Society's Examinations? [See the correspondence with H.R.H. the Commander-in-Chief of the Army, *Journal* p. 493]
5. The propriety of adding to the Society's Examinations the subject of "Practical Gardening," in accordance with a proposal made to the Council by the Royal Horticultural Society, who have expressed their willingness to offer prizes in this subject.
6. How can Institutions promote the Physical Education of their members?
7. How may Popular Readings and Entertainment be made to promote the efficiency of Institution Classes?
8. The advantage of Garden Allotments, as a feature of the Institute, with a view of healthful recreation to the members.
9. Should Institutes promote the establishment of Horticultural Shows, Building Societies, Penny Savings Banks and similar movements towards the social amelioration of the people?
10. The advantages and disadvantages of subscriptions to Institutes being paid by weekly or other small amounts.

The CHAIRMAN said it was now his duty to ask the Conference to enter upon the consideration of the various subjects which had been referred to in the report, and of those which had been suggested for discussion. But the proceedings went any further he could not help expressing his regret that on account of ill health they were deprived of the presence of Mr. Chester, who had for many years taken a most active part, and had been of the greatest possible service, in the system of Examinations which was now carried out by the Society. He regretted that he should be obliged to ask their indulgence in allowing him to leave the chair before the business was concluded. He then called on the Secretary to state the alterations it was proposed to make in

THE PROGRAMME OF EXAMINATIONS, ELEMENTARY AND FINAL, FOR 1866.

The SECRETARY stated that, looking at the small number of candidates that in each year had taken up the subjects of Conic Sections, Navigation and Nautical Astronomy, Astronomy, and Agriculture,

of elementary work, and they would be able to do that for thirty weeks in the year at a cost of £10, for which sum they could secure the services of a first-class man. He would then propose that they should have a special certificated teacher for special subjects at the central institution, at a cost of £12. Each institution would, under this scheme, have three class-nights under certificated teaching power, and one class-night under special teaching power.

Mr. C. WOMERSLEY (Hastings Mechanics' Institution) said the resolution merely served to affirm a principle about which no time need be wasted.

Mr. COLE said that if the resolution was supposed to mean that they recommended gratuitous teaching as a principle of action, he should have some objection to it. It was very well to get all they could for nothing, but everybody knew it was not likely to continue, and was not much prized after all. It was very important to make people who were being taught understand that what they were receiving was really something worth paying for, however moderate the charge might be. He did not like the use of the word "gratuitous," as it might be misunderstood, and he thought Mr. Blake could easily draw up a wider resolution which would embrace everything.

Mr. SALES (Metropolitan Association) thought it was a misnomer to call those mentioned in the resolution "organising teachers," because they not only had to set the machinery in operation, but they had to take part in working themselves. He should vote against any resolution which gave the authority of the Conference to the employment of gratuitous teachers. It was most desirable that the people attending the Institutions should feel bound to pay for the benefit they received from them, and not to trust to charity. He did not like to propose an amendment, but he hoped the resolution would not pass as it stood.

Dr. PANKHURST (Lancashire and Cheshire Union) said he thought they ought to embody in the resolution to be passed some substantive proposal, upon which they could fix the attention of the Conference. The substance of the resolution proposed by Mr. Blake was to assert that any system was better than none; but what they wanted to do was to show which out of the several systems submitted they believed to be the best. Mr. Lawton had very judiciously and effectually stated the points of difference between the plan which had received the sanction and approval of Sir James Kay Shuttleworth and the plan which was in partial operation in the Lancashire and Cheshire Union. The Lancashire system might be said to be the best for many obvious reasons. It was the simplest, the most economical, and the most productive of benefit, and these formed three very substantial reasons why it should be preferred. There were two subjects proposed to be taught, one of which might be termed general and the other special. The East Lancashire system gave to the same man both classes of work to do, while the Lancashire and Cheshire system gave to one set of men one subject, and reserved exclusively to the other set another subject. Mr. Lawton had stated the fact as to the money payments required by each Institution, and the same amount of work would be much better under the Lancashire than under the East Lancashire system; and for this reason, the object being that the special subjects should be taught in the best possible way, it seemed quite clear that each Institution should be pressed to supply its own staff of teachers for general subjects, and that the members of each Institute should be collected together under the management of a man who was devoted to one special class of teaching. He begged to move the following amendment to the resolution, as collecting together the principles of difference between the two systems:—

"That this Conference approves the system of organising teaching power through the Union by distributing Institutions into groups and a centre, at which special subjects may be taught, and suggests that each Institution should be pressed to establish a staff of teachers for general subjects."

Mr. BLAKE said the amendment was only his resolution put in another form, and he would at once withdraw his proposition.

Dr. PANKHURST said it was quite obvious that the number of special teachers they could command was very small compared with those who could be got to teach general subjects. The Lancashire and Cheshire had the advantage that while a special teacher was purveying instruction to one Union one night a week, and was so satisfying the wants of the Union, he might also be operating with the same efficiency for other Unions during the rest of the week, so that he might be purveying special instruction, of the best order and according to the most approved methods to five Unions in the same week, while at the same time a regular attention was paid to preliminary subjects, about which one might say that the higher they proposed to carry the point of special efficiency the broader still they ought to lay the basis of general subjects.

The Rev. R. WHITTINGTON (City of London College) seconded the amendment, and said that in the Institution he represented there was a fundamental rule that no teacher should be unpaid. He fully recognised the importance and the efficiency of paid teaching power, but on the other hand he knew there were many Institutions which were obliged to depend to a very great extent, especially in general subjects, on gratuitous teaching. He believed the system of organising teachers was one step in advance towards employing paid teaching exclusively, and he believed it was a system which would be productive of good results.

Mr. B. RULE (Aldershot and Farnham Board of Education) said he very much questioned whether it would be expedient on the part of the Conference to encourage the principle of gratuitous teaching.

The Rev. G. B. MACILWAIN (St. George's and St. James's, Westminster, Local Board) was fully sensible of the very great superiority of paid teachers over gratuitous teachers, but looking at the matter practically he thought they would all admit that for the present, at all events, they would be obliged to make very extensive use of gratuitous teaching. He found in his own Institution that they received very efficient aid from gratuitous teachers under the superintendence of paid teachers. He directed a great many classes, and in each room there was a paid teacher who was well skilled in the subjects being taught, and who had under him or her, as the case might be, ladies and gentlemen who were solely directed by the superintendence of the paid teacher, and to whom hints were given as to the way in which the teaching should be carried out. The system had been in operation for three or four years, and had worked well, the greatest harmony always existing between the parties engaged in it.

The Rev. W. S. BRUCE (St. Margaret's and St. John's, Westminster, Local Board) having had great experience in connection with night schools and evening classes wished to confirm what the last speaker had said. He fully admitted the usefulness of voluntary teachers, but he did not approve of schools where there were no paid teachers, because some one ought to be responsible for the general discipline and the tone of the education imparted. Still there were many cases in which it was absolutely necessary to employ voluntary teachers, and this was often the means of interesting parties in the school who would aid both pecuniarily and otherwise.

The CHAIRMAN said he did not think that by passing the resolution the Conference wished to discourage voluntary teaching, but only to declare that paid teaching was best. Whatever the Conference might say, however, it was a question which the various institutions would have to decide according to their individual circumstances.

Dr. Pankhurst's resolution was carried unanimously.

Sir F. R. SANDFORD then took the chair, and said the next subject was—

"IS ANY MODIFICATION OF THE PRESENT SCHEME OF ELEMENTARY EXAMINATIONS, BY RENDERING IT MORE ADAPTED TO THE CAPACITIES OF CLASS PUPILS IN MECHANICS' INSTITUTES, DESIRABLE?"

Mr. BARNETT BLAKE said he supposed it would only be necessary for the Conference to affirm by a resolution the statement in the report on this subject. As many would be aware, the great difficulty hitherto had been that while in many Institutions there were a great number of candidates who were sufficiently advanced in reading, writing, and arithmetic to show that they had got so far the basis of instruction, the present system required that they should have passed in other subjects, namely, Gospel History, English History, and Geography. It had been found in the practical working of this that while there were many who stood in a very respectable position with regard to the former they had a difficulty as to the latter, and it had been thought that it would really be an encouraging step if the condition was so far lowered as to make one subject alone necessary for the junior candidates. He did not think it was at all necessary to interfere with the senior candidates, because if they professed to be seniors they ought to have more knowledge than the juniors. He would merely propose to do this by saying that it was desirable to reduce the standard required for certificates for the junior candidates, and for that purpose he would propose the following resolution:—

That it is desirable to grant certificates to such junior candidates as, having satisfactorily passed in reading and arithmetic, shall also obtain a certain number of marks in one only of the subjects—Gospel History, English History, and Geography.

Mr. RULE much regretted that he was not at the Committee meeting yesterday at which this subject had been discussed, but he wished to suggest the introduction of another subject into the scheme of elementary education. He would suggest the very great advisability of introducing, both into the junior and the senior classes, English Grammar and Dictation. Many of the candidates were very well up in English History and Geography, but the general style of composition shown in the papers was very defective; and in many instances a large number of marks were lost by incorrect spelling. He believed that if English Grammar and Dictation were introduced it would materially improve the efficiency of the examinations; and in addition to that he would suggest that Composition should be introduced into the higher grade. He doubted very much whether any of the candidates who passed last year would be able to pass a satisfactory examination in English Composition, and he therefore wished the subject to be embraced, as well as Grammar and Spelling, in the examination.

The CHAIRMAN asked whether he would make it compulsory or voluntary.

Mr. RULE replied that he should prefer it to be compulsory.

Mr. LAWTON had understood the decision come to by the Committee applied both to the higher and lower grade of candidates. He understood that what was then said applied to both grades.

The CHAIRMAN said he had understood that the decision of the Committee applied only to the junior grade.

Mr. LAWTON said it should not be forgotten that many of the senior candidates were really the worst of the two. In fact, the seniors were those who had been neglected in years gone by, and the juniors were really the cleverest, they having but recently left school. With reference to females he had understood the scheme sketched out by the Committee to be that they would be required to take either Gospel History, English History, or Geography, but that they must be examined in reading, writing, arithmetic, and needlework.

Mr. FRANKALL (London Mechanics' Institution) expressed a hope that all the candidates might be given clearly to understand what they were to be examined in, because it would be exceedingly annoying to them, when they had

prepared for a certain examination, to find that more would be required of them than they had expected or were prepared for. In many cases the examiners rubbed up their own education to prepare the questions, which was unfair indeed to the candidates, who had not had equal advantage with the examiners. If the English language were taught on a better principle than that at present adopted it would be different, but on the system on which it was taught at present it was impossible that the candidate could be expected to pass a satisfactory examination in it.

Mr. SALES said it appeared that he had made a great mistake as to the decision come to yesterday by the Educational Committee, for he had quite understood, when voting for the resolution, that the reduction to one subject applied to both grades, or else he should certainly have opposed any resolution which did not apply to the higher grade. He spoke from his experience of a metropolitan district, where he found that the number of classes increased very considerably, and that those classes were well attended by the very persons whom they wished to get at. A man looked through the programme of the Society of Arts, and found that if he obtained a certificate from a District Union he need not pass another examination before undergoing the Final Examination of the Society; but when he looked to the requirement for the certificates he found that he was expected to have a smattering of English History and Geography, and he then asked why he should be expected to get himself up in those subjects when he only wished to undergo an examination by the Society in a subject in which he was engaged in his daily occupation, and with which English History and Geography had no connection whatever? This condition of requiring English History and Geography had greatly affected the elementary examination of the past year, and would do so still more in the future, and therefore, as a step in the right direction, he had voted yesterday that it should be made compulsory next year to take only one subject, and he hoped the time would come when it would not be thought necessary to make either English History or Geography compulsory on the candidate for examination. He hoped the system would be made something like the examination in honours, by allowing the candidate to take those subjects if he pleased. He was certain that if the Society of Arts continued to require English History and Geography in the Elementary Examinations, the District Unions would find that such a system was detrimental to the candidates themselves. He begged, therefore, to move, as an amendment:—

"That it is important that the Elementary Examinations should be more adapted to the capacities of class pupils in Mechanics' Institutions, by not rendering it compulsory in either grade to take up more than one of the three following subjects, viz.:—Geography, History, and Gospel History, in addition to Reading, Writing, and Arithmetic."

The CHAIRMAN said he had certainly understood yesterday that the resolution withdrawing one of the subjects for examination referred only to the junior grade, but he did not know whether Mr. Blake would have any objection to making his resolution applicable to both grades. He would, therefore, ask him whether he objected to leaving the word "junior" out of his resolution.

Mr. BLAKE thought no one could have misunderstood the decision of the Committee. He objected to the proposal that the alteration should apply to both grades. He disagreed with the reasons on which the proposal was made. It was one of the great crying sins of the day that in all the public questions which were being continually brought up people knew so little about history and geography, and why should they have certificates granted to them when all they knew might be a little reading or arithmetic? When the question was raised some time back as to the female candidates and the necessity for their passing an examination in plain needlework, the objection taken by some members was that they had

a right to consider the class for whom the examinations were established. He believed they would not be doing their duty if they neglected branches of education so necessary for the improvement of the people. The word "junior" in connection with the candidate did not apply to age at all, but only to attainments. If the candidates claimed a certificate of a higher grade, which supposed that they had acquired, at least, the elements of an English education, it was but fair to expect of them that they should learn something of the broad facts of history and geography. The plan which Mr. Rule had proposed would make the matter more difficult still, and there was really no necessity for it, because the quality of the composition could be judged from the answers given to the various questions. He did not believe there was a greater popular error than that of learning Grammar; and he did not believe that such a system as that proposed could be carried out successfully, though he admitted that there might be some good done by introducing Dictation. He did not consider that the necessity of having two subjects compulsory need be regarded in any way as a bar to the Local Boards returning candidates to the Final Examination of the Society of Arts, and he should therefore press the resolution which he had proposed.

Mr. PRANSALL wished to state, from his own experience, what the state of matters was. At the present time there were young men who had entered themselves for the Society of Arts Examination in Arithmetic, but who had been rejected on the critical points of Dictation, Writing, and Grammar, and who were now answering questions on arithmetic in the public periodicals, though they could not obtain a certificate from the Society of Arts.

Mr. LAWSON said he should like to reply to one or two things that had been said by Mr. Blake. He maintained that the Programme was not sufficiently distinct, but was too loose in its character, spreading over the whole of history as it did for the lower grade, and merely taking a period of fifty years for the higher grade. What he had stated before on this subject was that the modified scheme should bear entirely on the whole system of examination, including both the higher and the lower grades. He could also say that there many institutions which would not adopt the present scheme of Elementary Examinations as the preliminary for the Final Examination. In fact, many of them had told him that if the present system continued they should take no notice at all of the Elementary Examinations, but take the matter entirely into their own hands, and conduct their own Previous Examination. Many of the candidates were willing to join for one special subject which they had been studying, it might be History or Geography, or Chemistry, but they would not go in for two. They could not do it, and not only that, they would not do it. If the Elementary Examinations only required Reading, Writing, and Arithmetic, allowing any other subjects to be optional, he believed the candidates would avail themselves of the examinations to a greater extent than they had hitherto done.

Dr. PANKHURST said he had looked with a great deal of care at the amendment proposed by Mr. Sales, and he felt bound to concur in it. The purpose they had in view was to state substantially what was to be the matriculation examination to the Final Examination of the Society of Arts. It was perfectly plain that the class from whom to exact a variety of subjects was the young people, and yet Mr. Blake was not disposed to do this, though he wanted to subject the labouring people, who ought to be exempt, to a severe test in subordinate matters. If a mechanic presented himself for examination it was quite obvious that they ought to expect as little from him as possible, considering that he was probably advanced in years, and had contracted certain mental habits which it would be difficult for him to overcome. He thought that from such a man they might fairly exact Reading, Writing, and Arithmetic, and one other subject which he should be required and expected to prepare himself in as a matter

of intellectual culture. He felt satisfied that the amendment of Mr. Sales was one which would commend itself to the Society, and he had much pleasure in seconding it. It was very necessary to bear in mind that the preliminary examination was substantially a matriculation, and as they were approximating middle-class education to university education, so they also ought to approximate industrial education to middle-class education. He wished to impose on the instruction in every Mechanics' Institution all the conditions which were proper to an efficiently-conducted middle-class school.

Mr. JONES (South Staffordshire Association) said it seemed to be assumed that the Local Boards and District Unions must accept the senior certificate and then pass the candidate for the Final Examination. All the Society of Arts said was that they would accept such certificates, but the fact was that in many cases, if not in the majority, the Local Boards had their own special examinations. He could not see how it was at all upon the question of Final Examinations, while they had one or two subjects. It was just as well to ask a candidate coming up for examination in chemistry, or in a scientific subject, to take up one of the three subjects as it was to take up two, as in requiring the three, as proposed by Mr. Rule, they were really putting another condition for the admission to the final examination. The Society of Arts only required an examination in certain subjects which had been sketched out, and if they adopted a senior certificate the candidate had the option of being examined in any other subject besides the special subjects required by the Society, and the Local Boards were urged to encourage candidates to take the senior examinations because it would simplify the matter. It would be found very convenient in some institutions to make the Previous Examination altogether independent of the senior examination. With respect to what had been done by the Committee, he quite understood that the senior programme was not to be changed at all, and if it had been intended to have been altered he should have spoken against it, because he was instructed by the Institution which he represented to put only for a change in the junior programme. It was of great importance that there should be some difference between the senior and junior programme, and he thought the Conference would only be doing its duty in approving the modification proposed by the Committee.

The Rev. W. S. BRUCE did not believe that by having two subjects compulsory they would produce any high state of education, because the greater the number of subjects a candidate was allowed or compelled to go in for, the more would he be likely to get only a smattering of each of them, while he would really know but very little about them. He had been examiner to one local board, and the atrocious answers that were given by the candidates in Gospel History, Geography, and English History were beyond what one could possibly have imagined could have been the case.

Mr. E. HAY CURRIE (Metropolitan Association) supported Mr. Sales's motion, though he did not agree with it *in toto*, but he believed it to be a step in the right direction. They had attained considerable results in the east of London during the past winter, but it was found that it was no use whatever trying to do anything with History and Geography. A large number of candidates wished to go in for the examination, but they asked what was the use of their being examined in History or in Geography. He quite agreed with what had been said about English Grammar. He believed that if the subject could be substituted for History and Geography, it would be a very great step in advance. He had had a class of about 60 or 60 lads, about 16 years of age, in English Grammar, and it was a very popular class indeed. There was a very strong competition at the end of the season, but the members positively declined going in for the other subjects.

Mr. BLAKE said he did not think it should be con-

dered that the plan proposed was to be a pass to the higher examinations. What he wanted to do was rather to give an intermediate certificate, and this was a reason why it had been somewhat modified.

Mr. LAWTON said that in his district they were trying to do away with so many examinations being held.

Mr. RULE said they were not obliged to hold them.

Mr. LAWTON replied that they must have a test examination if they had not a preliminary one, or else how could they say that such and such a candidate had passed. They were trying as much as they could to amalgamate the Examinations, by doing away with some of the Local Preliminary Examinations.

Mr. SALES said, in reply to the chairman, he felt bound to press his amendment; English History and Geography, he considered were put quite out of court, because they were both on the papers of the Society of Arts, to the Final Examination of which it was intended to lead the candidate on.

The Rev. B. WHITTINGTON seconded the original resolution *pro forma*.

The amendment was then put and carried.

Mr. RULE then proposed his resolution as a separate motion:—

"That English Grammar and Writing from dictation be introduced into the Junior Grade, and that the same subjects, including Composition, be added to the Higher Grade, such subjects to be obligatory."

He said that some of the speakers seemed to think that English History and Geography were the only subjects by the study of which a young man could acquire mental discipline, forgetting that, in the way in which English Grammar was now taught—which was very different from what it used to be—nothing could be better for the purpose of mental discipline in those who studied it. It was now taught in a reasonable and philosophical manner, and the mental good to be gained by so studying it was far greater than that introduced by the study of English History and Geography—two subjects which could be very easily got up by students, whereas Grammar could not be, but must be thoroughly understood before a satisfactory examination could be passed. Mr. Blake said that they could judge by the examination papers of the character of the candidates' composition, but he could assure Mr. Blake that he was very much mistaken about that. He had for several years revised the papers sent by the Society of Arts down to Aldershot for the Elementary Examinations, and he knew that those who replied to those papers were certainly able to write a decent composition, in fact he very much doubted if three out of four of them could write a description of the town of Aldershot. It was a very sad thing that a young man should be entering life without being able to write a description of the town in which he lived, and he believed this matter was one of great importance. The matter of dictation, too, he thought, was a very important one. He did not mean by composition that they should require from a candidate an elaborate essay on Virtue, but a simple description of a town or a game, so that they might be able to judge of that power he had of expressing his thoughts.

Mr. SALES asked if Mr. Rule would make his resolution simply permissive instead of compulsory.

Mr. RULE said he was willing to do that, in the hope that at some future time it would be made obligatory.

The Rev. R. WHITTINGTON thought the Dictation ought not to be dropped, because it was a much better and more difficult thing than mere Spelling, as had been suggested, and had been adopted now in the public schools. Notwithstanding what had been said about Grammar, he believed that the subject, as it was now taught, was a most important one, and he quite agreed that it ought not to be ignored, though for the present it would perhaps be as well not to make it compulsory.

Mr. PEARBALL said it would perhaps answer the purpose

if it was understood by the candidates that the examiners would append to the papers such remarks as they thought fit upon the Composition.

The CHAIRMAN asked if the gentlemen who were supporting the resolution had considered that it would involve a special night? If there were four subjects, and the candidates could take any two of them, they must have a separate night for each.

The Rev. W. S. BAUCE said that might easily be obviated. As the term "Dictation" had been objected to, he would suggest that it should be altered to "Writing from Dictation," and then no one could possibly make a mistake about it.

Mr. LAWTON thought that after the last resolution which had been passed it was hardly advisable to take in another subject, though he approved of Dictation, because it would not involve a separate night, nor any special preparation on the part of the candidates. He did not think it was desirable to introduce Grammar.

Mr. BLAKE strongly advised the Conference to reject the resolution, because if it was passed they would be virtually debarring the candidates from passing the examinations. It was clear enough that a candidate could not write an interesting description of the town of Aldershot if he could not answer a question in English History. Mr. Rule said that the replies to the papers were no test, and yet the very next minute he said that he had already tested the composition of the candidates by their papers. It was all very well to talk about Grammar, but the fact was that the best of our modern writers were those who had never learned Grammar at all. He protested against the introduction of Grammar and Composition, because it would keep the candidates from coming up to the examinations. Dictation he did not so much object to, but they might depend upon it that the more of these things they imposed on the candidates the more breaches of the regulation they would have. He was sure that nothing would be gained if the resolution were carried.

Mr. W. H. CURRIE had much pleasure in seconding the resolution.

Mr. SALES supported the resolution, and thought the remarks of Mr. Blake were utterly beside the question, inasmuch as it was not proposed to substitute English Grammar for one of the other subjects. He believed he should send far more candidates for examination in Grammar than in all the other subjects combined; and as the resolution was so very mild, seeing that it was only permissive, he hoped Mr. Blake would withdraw his opposition to it.

Mr. BROOKS (Banbury Mechanics' Institution) thought it might not be desirable to increase the number of subjects for examination, inasmuch as there would be great difficulty in getting examiners. He should be very glad to find English Grammar introduced, but he should be sorry if it had the effect of injuring the present examinations, or of preventing candidates coming forward. He was afraid that in many provincial towns this would be the case.

Dr. PANKHURST believed that consistently with the previous resolution it was highly undesirable to increase the number of subjects, and he thought that a great part of the good which it was thought would arise from introducing another special subject would be effected by informing the candidates, by a memorandum appended to the papers, that special attention would be paid by the examiners to Grammar and Spelling. He objected to the introduction of Grammar as a special subject, because it was so very vague. It by no means followed because a large number of candidates might be sent up that an useful examination would take place, because such an examination was exceedingly difficult. He hoped, therefore, that the Conference would not pass the resolution.

The CHAIRMAN said that in the Paddington Institution, with which he was connected, there was great difficulty in getting persons to superintend the examinations, and, therefore, he should be sorry to see the number of nights

added to. He should be sorry for Dictation to be introduced unless it were made obligatory on both classes of candidates. He quite agreed that Grammar was the most difficult subject which could be introduced, and it was one which was now disappearing from many of the public examinations.

The Rev. W. S. BRUCE suggested that the Chairman should ask the Society of Arts to strengthen the present programme by calling special attention to the subjects of Grammar, Spelling, and Composition.

The Rev. R. WHITTINGTON said the Society had already done all that they could in this matter.

The resolution was put to the meeting and lost.

Mr. G. F. WILSON, F.R.S., then took the chair, and announced as the next subject for discussion—

"THE ADVANTAGES OF LOCAL PRIZES TO SUCCESSFUL CANDIDATES, AT THE SOCIETY OF ARTS EXAMINATIONS, AS A STIMULUS TO LOCAL COMPETITION."

Mr. BLAKE said the resolution he should move on this subject was as follows:—

"That in all cases where the means for local prizes can be obtained it is desirable to offer them as a stimulus to local competition, to be decided by the result of the Elementary and Final Examinations of the Society of Arts."

He did not consider that it was at all necessary to enforce the great advantages of stimulating candidates in order to induce them to exert themselves so as to be as successful as possible. He believed there would not be the slightest difficulty in providing local prizes, but that there were many gentlemen who would be glad to subscribe funds for such a purpose. One very important part of the arrangement would be to see that the prizes were distributed by a thoroughly competent and impartial authority. The resolution merely affirmed the propriety and desirableness of establishing such a system of local prizes as had been found to work well in the Yorkshire Union.

Mr. BROOKS seconded the resolution. He said that their experience at Banbury had been decidedly in favour of granting local prizes to those who had obtained first-class certificates from the Society of Arts or from the Department at Kensington. This system acted as a great stimulus to local candidates, who were certainly deserving of some consideration on the part of those who lived in the town where the Institution was established, and were glad to receive such expressions of sympathy and of approbation. There was an idea in many places that the examinations of the Government Department and of the Society of Arts were rivals, but such was not the case, and at Banbury the starting of the Science School in connection with the Institution had been of great advantage to them, and it had been found that the two mutually assisted each other.

Mr. CRAIG (Glasgow Institution) said that the Institution which he represented had a very strong feeling on this matter, and most earnestly wished the resolution to pass.

The Rev. R. WHITTINGTON could not understand to whom it was intended to give the local prizes, or how it could be a stimulus unless it were given to the second-best man, whose name was never known. The prize of the Society of Arts was stimulus enough to the successful candidate.

The Rev. W. S. BRUCE said the only way in which they could make the local prize a stimulus was by knowing which of their local candidates did the best.

Mr. BLAKE said the object was not to ascertain who the second-best man was, but to give a local prize to the local successful candidates.

Mr. SALES said the system now proposed was already carried out in connection with the Metropolitan Association, prizes being given to the successful London candidates, as shown by the number of marks awarded by the Examiners.

Mr. RULE said that for the first time this year Sir

Charles Wentworth Dilke had given a prize of £5 to the candidate from the Aldershot Institute who obtained the highest aggregate number of marks at the Society of Arts examinations. Every first-class certificate was counted as four marks, every second as two, and every third as one. The same prize had also been promised for next year.

Mr. REYNOLDS (City of London College) said he was connected with three Institutions, and the plan adopted in one of them, the City of London College, was to have local examinations for the local prizes. He thought there would be some difficulty about the scheme as proposed, because they might get several members of one Institution who obtained precisely the same number of marks or certificates, and the question would be, which of them was entitled to the prize. This, perhaps, would not apply to small, but only to large Institutions, where it would be found a very hard matter indeed to arrange candidates in the order of merit, and he did not suppose that the Society of Arts examiner, considering the amount of work he had to do, would be willing to take the trouble of telling them in each case the number of marks gained by the candidates.

Mr. SALES said the Society of Arts supplied him with a list of candidates arranged according to their respective merits.

Mr. BLAKE said he did not believe that such a case had been mentioned by Mr. Reynolds would ever arise.

The Rev. R. WHITTINGTON said, that surely one small Institution might send up two men who would take the same class of prize.

Mr. REYNOLDS said, that at the Polytechnic Institution they had more money to distribute in prizes than they could advantageously. In another Institution, at Bromley, there were two pupils this year who had first-class certificates for Arithmetic and Book-keeping, and he would ask Mr. Blake what he would do in such a case as that.

Mr. LE NEVE FOSTER (the Secretary) said it would perhaps save time if he stated at once that any Institution which desired the information could be furnished with the order of merit of its candidates.

Mr. BROOKS said that at Banbury every first-class certificate was supplemented by a local prize.

The resolution was carried.

"WHETHER ANY SPECIAL INDUCEMENTS CAN BE HELD OUT TO LEAD SOLDIERS TO AVAIL THEMSELVES OF THE SOCIETY'S EXAMINATIONS?"

Mr. SALES said he wished to move a resolution on this subject on the part of Mr. Chester. The matter had already been published in the *Journal*, and if the resolution was carried it would only be extending the area of the Society of Arts examinations, and add to the prestige and the work of the Society. The resolution he had to propose was as follows:—

"That the Conference welcome the sanction of His Royal Highness the Duke of Cambridge to the scheme of education carried on by the Society of Arts. In the opinion of the Conference, however, it is important that no inducement should even be suggested without previous consultation with the Commander-in-Chief or with the Military Council of Education. They also think that Local Boards at military stations should be cautioned not to take any initiatory measure without first engaging the concurrence at least of the general or other officer commanding, or, in the case of a regiment, of the officer commanding that regiment."

Mr. RULE had great pleasure in seconding the resolution. At Aldershot they had hailed with very great satisfaction the memorandum issued by the Commander-in-Chief, but at the same time they knew by experience that it was necessary to be extremely cautious as to the manner in which they proceeded in working among soldiers. If the plan were carefully and judiciously worked it would no doubt be a great advantage to the soldiers, but if not it would prove to be a very great disappointment to them.

selves and to the Society of Arts. The soldier knew only one master, and that was his commanding officer; he had no less sense of right, or moral feeling, or sensibility than the civilian, but his commanding officer was everything to him, and he would do nothing without his sanction, or unless he was ordered by him. Of course it was necessary that discipline must be maintained in the army, but some of the officers were remarkably strict, and many of them even went so far as to maintain that the soldier was "none the better for being educated." If they went to work incautiously they might depend upon it that the memorandum issued by the Commander-in-Chief would very soon be withdrawn, and nobody would know why. The only thing to do was to leave the whole matter to the local board, and to let them work it as their experience might tell them was best.

Mr. WOMERSLEY (Hastings Mechanics' Institution) knew nothing of the matter more than he had seen in a memorandum, but if it was such a difficult matter why should they interfere in it at all? He should certainly never ask an officer himself whether he might teach his men or not.

Mr. FRASER said, that in the London Mechanics Institution they had had several instances of the willingness of soldiers to avail themselves of the advantages offered there; and several years ago some members of the Horse Brigade, stationed at Windsor, used to walk from Windsor to attend the evening classes, and march back after the classes were over.

Mr. NOLDWITT (Walworth Institution) said he understood that the soldiers at Aldershot complained a great deal of the want of lectures.

The resolution was carried.

THE PROPRIETY OF ADDING TO THE SOCIETY'S EXAMINATIONS THE SUBJECT OF "PRACTICAL GARDENING," IN ACCORDANCE WITH A PROPOSAL MADE TO THE COUNCIL BY THE ROYAL HORTICULTURAL SOCIETY, WHO HAVE EXPRESSED THEIR WILLINGNESS TO OFFER PRIZES IN THIS SUBJECT.

The CHAIRMAN said that Mr. Chester took a great interest in this subject, and if he had been able would have been present to have spoken upon it. For his own part, he had lately been thrown a great deal into contact, as a member of the Fruit Committee of the Horticultural Society, with many of the practical gardeners in the country, and he could not help noticing how great a difference there was between those who were educated and those who were not. The Society of Arts were willing to do all they could to encourage education in gardening, and the resolution to be proposed would affirm the desirability of their so doing.

Mr. RULE proposed, and the Rev. R. WHITTINGTON seconded a resolution expressing the opinion of the Conference in favour of such a course, which was carried.

"HOW CAN INSTITUTIONS PROMOTE THE PHYSICAL EDUCATION OF THEIR MEMBERS?"

Mr. BLAKE proposed the following resolution:—

"That, in the opinion of this meeting, the physical education of the members of Institutions may be beneficially promoted by the formation of classes for the practice of cricket and other athletic exercises, excursions for the study of botany, geology, and cognate sciences, and similar pursuits adapted to summer time."

He thought that much good might be done in establishing games in connection with Institutions, especially during the summer months, when people wanted to get out of doors, and the Institutions and classes were generally neglected. It was not altogether a new thing, and was very effective in keeping the members together.

Mr. SALES heartily seconded the proposition. The Metropolitan Association which he represented had already taken the matter up, and though there were great difficulties in carrying out anything of the kind in a place like

London, they had done all they could to overcome them. They had encouraged the exercise of athletic sports, and about twelve months ago they had a *fête* at the Crystal Palace, and though they did not expect to be very successful they were pleased to find that they attracted 13,600 visitors. They were shortly going to have another *fête* at the same place, when they would have a competition in athletic sports, to which they invited their friends from the country. Although they would only be able to give prizes to their own members, they were quite willing to form the nucleus of a fund for the purpose of providing a prize which should be open to the members of any Institutions to compete for.

Mr. REYNOLDS said the great difficulty in respect to this matter in London was the want of funds. The Institution doing most in this way was one at Bromley, where they had a cricket field for which they paid a high rental. For his own part he advocated an entire cessation from study during the summer, and he therefore advocated the establishment of some system for promoting the physical education of the members of the Institutions during the summer months.

The resolution was carried.

Mr. JONES said the next subject had been suggested by him, and was as follows:—

"HOW MAY POPULAR READINGS AND ENTERTAINMENTS BE MADE TO PROMOTE THE EFFICIENCY OF INSTITUTION CLASSES?"

All he wished to do was to ask the various representatives present whether they had found popular readings and entertainments promote the efficiency of the Institutions and the classes. He wished to get information on the subject.

The Rev. R. WHITTINGTON said this matter had always been a difficult one to carry out, but on the whole he was of opinion that popular readings and entertainments did promote the efficiency of Institutions, and for this reason it was very important that the members should feel that they had a kind of associated feeling in connection with the Institutions, and this could be done by giving them opportunities of inviting their friends to visit the Institutions on certain occasions. The benefit of elocution classes was sometimes doubted, but on the whole he thought they were of use, and it must be remembered that many of those who were members of the elocution class would not visit the Institution at all if no such class existed.

Mr. BLAKE said that in his experience he had found popular entertainments to be highly successful, even where class instruction was made an important feature of the Institution. After giving some results of popular entertainments in connection with the Institution at Huddersfield, Mr. Blake moved the following resolution:—

"That popular readings and intellectual entertainments may be made to promote the efficiency of institution classes by being given at fixed times, by being varied with the practice of music classes, and by brief discussions for the encouragement of English Composition on subjects bearing reference to the objects of the Institution."

Mr. CRAIG seconded the resolution.

Mr. RULE said that great attention ought to be paid to the subjects chosen for readings, and he thought that the people who carried out such readings often wanted advice on this subject.

Mr. BROOKS thought the Society of Arts would be doing great service if they would publish a guide as to what works were suitable for public readings.

The resolution was carried.

"THE ADVANTAGE OF GARDEN ALLOTMENTS AS A FEATURE OF THE INSTITUTE, WITH THE VIEW OF HEALTHFUL RECREATION FOR THE MEMBERS."

Mr. BLAKE said in some districts it had been found that the plan worked well, and nothing could be more desir-

able than that it should be introduced generally wherever practicable, inasmuch as it would be greatly for the benefit of the members of the Institutions, and would also promote the study of botany. He would therefore propose—

"That, wherever practicable, it would be of advantage to the members for Institutes to provide garden allotments, under regulations, in which due cultivation and prompt payment of rent were prominent features."

Mr. PEARSALL seconded the resolution, and bore testimony to the efficient state in which he had found this system to be in in Yorkshire.

The CHAIRMAN said that within four miles of Birkenhead he had seen a piece of ground of about thirty acres let out in allotments on the plan proposed, and with the happiest results to the Institutions with which it was connected.

The resolution was carried.

"SHOULD INSTITUTES PROMOTE THE ESTABLISHMENT OF HORTICULTURAL SHOWS, BUILDING SOCIETIES, PENNY SAVINGS BANKS, AND SIMILAR MOVEMENTS TOWARDS THE SOCIAL AMELIORATION OF THE PEOPLE?"

Mr. BLAKE proposed, and Mr. WINKWORTH seconded, the next resolution, which was carried as follows:—

"That Institutes may with great advantage promote the formation of Horticultural Shows, Building Societies, Penny Savings Banks, Provident Societies, and similar means of ameliorating the condition of working people, and also provide accommodation for the payment of wages."

"THE ADVANTAGES AND DISADVANTAGES OF SUBSCRIPTIONS TO INSTITUTES BEING PAID BY WEEKLY OR OTHER SMALL AMOUNTS."

Mr. NOLDWORTH said the question of receiving the payments in small sums would depend greatly on the class of people who were the members of the Institutions, and it must be left entirely to each Institution to decide for itself.

Mr. REYNOLDS thought that, as a general rule, the payments ought to be made every three months at least, but there were circumstances, perhaps, in which shorter payments would be necessary.

Mr. CRAIG said that the Institutions which he represented were of opinion that wherever it was practicable the payments should only be made once a year.

Mr. PEARSALL said it was a matter which must depend entirely on the locality in which the Institutions were placed.

The resolution was carried.

Mr. BLAKE then proposed, and Mr. F. TALBOT seconded, the following resolution, which was passed unanimously:—

"That the delegates present at this Conference desire to express their high sense of the valuable services to Institutions rendered by the Society of Arts by the system of Elementary Examinations and the Certificates and Prizes at the Annual Final Examination, by which the important cause of adult education has been very greatly promoted, and they request the Council of the Society of Arts to accept their cordial thanks for the important aid which has thus been given to the Institutes in association."

Mr. NOLDWORTH asked if the attention of the Society had been called to Mr. Lock's Theatre Bill, which, if carried, would oblige every lecture-room in the kingdom to be shut up as useless.

Mr. LE NEVE FOSTER (Secretary) said it was no doubt a very important matter for the consideration of the Institutions, and he was glad it had been mentioned, but it was understood that for the present the Bill was withdrawn.

A vote of thanks to the three gentlemen who had presided over the Conference was then proposed by Mr. RULE, and seconded by Mr. REYNOLDS, and carried unanimously.

The CHAIRMAN returned thanks.

Fine Arts.

ENGLISH TASTE AND ART.—M. Michel Chevalier, in a debate in the French Chamber on the 20th May, advocating increased exertions in France, said:—"It is now three years since I was in London, as a French member of the jury for the International Exhibition, I give the names of my honourable colleagues on that occasion—MM. Le Baron Gros, Merimée, and Dumas, who I see are now in their seats, and from whom I ask co-operation. The one fact more than another which particularly struck the French jury was the considerable progress made by foreigners in the art of design in connection with industry. We were struck by it; it inspired us with admiration for the efforts made by foreigners, but it likewise inspired us with a fear that our country might be out-done. We were impressed and frightened by the marked progress with which the English had notably made in works of good taste. The English up to recent times, although they had had some celebrated artists, have not been very remarkable for taste; and good taste was wanting in their industry. The greater portion of designs used in the printed cotton manufactories at Manchester and Liverpool came from designers established in Paris. The English have understood that, during this industrial competition between the different foreign nations, it was necessary to make great efforts, and they have made them. A museum has been established at South Kensington for the purpose of educating teachers, who are afterwards sent throughout the manufacturing towns of the country; in propagating good taste a revolution has been effected. We were so much surprised at the progress made that when our report had to be drawn up, one of us (and he by no means the least competent in matters of taste, M. Merimée) treated this point specially, and certainly what he has written is one of the most curious and best written pages of the six volumes which comprise the general report of the French jury. From the three or four lines which I am going to quote to you, you yourselves will appreciate what the English have done, and will better understand the information laid before us, and the obligation under which we are of redoubling our energies so as not to compromise our superiority. 'The school at South Kensington has been open for ten years. The corresponding provincial schools (and others which might have been added, to which masters have been sent) numbered ninety. The number of students trained throughout the United Kingdom was 91,386.' (M. Merimée—These numbers which were for 1862 must have now greatly increased.) M. Michel Chevalier continued—'With respect to the influence exercised in so short a period by this great institution, we admit freely the assistance rendered to us by our colleagues in the English jury. In answer to our question as to the cause to which the progress so remarkable that year in their manufactures were attributed they replied, the new resources opened to industry by the schools at South Kensington.' I conclude by quoting that 'the study of drawing and of mathematics is the foundation of the instruction which should be given to the students.'"

POMPEII.—An interesting discovery has just been made at Pompeii, where the face of a large and handsome fountain has been uncovered. Connected with this a very curious fact is given, namely, that the upper portion of the fountain is covered with zinc, a metal which has not been supposed heretofore to have been applied to any such purpose. It is proposed to restore this fountain, which is decorated with shell work, in order to show the character of public works of the kind at the Pompeian period.

Commerce.

THE COAL MINES OF THE WORLD.—M. A. Burt, in a work entitled "Situation de l'Industrie Minière"

1864," gives the following as the statistics of the extent of known coal fields and their annual production :—

	Extent in hectares (1 hectare being equal to 2·471 acres)	Tons.
British Isles	1,570,000	86,000,000
France	350,000	10,000,000
Belgium	150,000	10,000,000
Prussia and Saxony	300,000	12,000,000
Austria and Bohemia ...	120,000	2,500,000
Spain	150,000	400,000
North America	80,000,000	20,000,000
Total	32,640,000	140,900,000

As regards France, the coal basin of the Loire, which is only 25,000 hectares in extent, furnishes three-tenths of the whole of the coal raised in the country.

Colonies.

WATER CONSUMPTION IN MELBOURNE.—According to a statement made in Parliament the other day, the quantity of water consumed in Melbourne and the suburbs every twenty-four hours is 9,750,000 gallons, being at the rate of 90 gallons per head per diem, or a larger consumption per head than takes place in any other city in the world, save Rome, Marseilles, and New York.

ACCLIMATISATION IN VICTORIA.—At a recent meeting of the Acclimatisation Society, at Melbourne, a letter was read, bringing under the notice of the Council the eminent adaptability of the Bogong Mountains for the liberation of deer. The Bogongs are a range of mountains on the north-east of Victoria, consisting in many parts of basaltic plains, between 3,000 and 4,000 feet above the level of the sea. They extend from the river Murray to Gipp Land, run north by south-west, and abound with wild fastnesses, from which, if the deer were once established, it would be almost impossible to dislodge them. The letter concluded by saying that, "if this object be successfully achieved, next to the introduction of salmon nothing of such importance in the country will have been effected; a valuable tract of mountains, miles in extent, will become of use; deer-stalking, not inferior to any in Scotland, will be afforded, and an inducement to visit wild and romantic scenery in a cold climate will be offered." This letter it was decided to take into a fuller consideration at a future meeting. It is evident that a great number of deer must be enlarged at once to give any chance of the breed being firmly established in such a country; and with this object in view the secretary was requested to make inquiries as to the feasibility of importing a number of fallow deer from Tasmania.

Obituary.

ERENNE GÉRUZZE, late Professor of Literature at the Sorbonne, and since Honorary Professor of the Faculty of Letters, died in Paris recently. M. Géruzzé was a man and prolific writer, and enjoyed a high reputation as a critic and literary historian. His best works are a "History of Political and Religious Eloquence in France in the 14th, 15th, and 16th centuries;" a "Complete course of Education for Girls;" and the recently published "History of French Literature to the year 1789;" which last, if we are not mistaken, won for its distinguished author one of the great prizes of the French Academy. His funeral was attended by an immense number of literary men.

Notes.

COMMERCIAL EDUCATION IN FRANCE.—The Chamber of Commerce of Paris has recently established an institu-

tion that deserves attention, a school specially designed for youths intended for financial and commercial pursuits. Besides those branches of knowledge which are absolutely necessary for success in finance and commerce, the modern languages, English and German in particular receive special attention. The new school is in full operation, and was visited the other day by M. Duruy the Minister of Public Instruction, who is indefatigable in his endeavours to improve the means of public instruction. The establishment is on a grand scale and is situated in the Avenue Trudaine.

CAB!—In Paris, as in London, there are great complaints upon *fête* days, in bad weather, and at all times when public conveyances are in great requisition, that while the omnibuses exhibit a board bearing the word *complet* when they are full, there is nothing to tell whether a passing cab is engaged or not, and this affords the drivers the opportunity of being deaf to applications which do not quite coincide with their own views as regards direction, numbers, or otherwise. It is now proposed to remedy this by affixing to the cab a flat lamp, of a brilliant colour, so as to form a day as well as night signal, and so arranged as to be seen only when the vehicle contains no passengers.

NEW FORM OF HONOURING GENIUS.—The great French chemist, Thénard, was born in a village in the arrondissement of Nogent-sur-Seine, in the Aube, which was called La Louptière, on account of the immense number of wolves which formerly invested it. He was the son of a poor farmer, and was born on the 4th of May, 1777. Having studied chemistry under Fourcroy at the Jardin des Plantes in Paris, he eventually occupied the chair in the Academy of Sciences, rendered vacant by the death of his master, was created a baron by Louis XVIII., and died in 1857, crowned with all the honours that science had to bestow. His native village has applied for and obtained permission to honour his memory by appending his name to that of the place of his birth, which is for the future to be called La Louptière-Thénard. A grand *fête* was held there on the 21st of May to celebrate the event, when the new name was officially published.

SCIENTIFIC ASSOCIATION OF PARIS.—This new society, whose proceedings have been already noticed more than once in the columns of the *Journal*, has just made its first annual report. The subscription to the association is only ten francs a year, and the smallness of the rate has in this case produced highly satisfactory results. Besides defraying the expenses of a series of monthly meetings, and the cost of the experiments performed on those occasions, the association has been able to apply a sum equal to £840, in three equal amounts, to the encouragement of astronomy, physical science, and meteorology; this distribution of funds has already been noticed in our columns. The portion devoted to astronomy is for the purpose of constructing a large telescope. A portion of the sum devoted to meteorology has been voted to several Dutch and French sailors for observations at sea, and valuable in the construction of storm charts, and in the elucidation of the laws which regulate such atmospheric phenomena. M. Terquem, of Metz, reported to the association, at its last meeting, the first results of his experiments, undertaken with the aid of the society, on the vibrations of metallic rods and plates. The Scientific Association of Paris consists at present of three thousand five hundred members, which, it is hoped, will be more than doubled next session.

Proceedings of the Society.

ANNUAL GENERAL MEETING.

The Annual General Meeting for receiving the Report from the Council, and the Treasurer's statement of Receipts, Payments, and Expenditure during the past year, and also for the election of Officers, was held, in accordance with the Bye-laws, on Wednesday, the 28th inst., 4 p.m. WILLIAM HAWES, Esq., Chairman of the Council, presided.

The Secretary having read the notice concerning the Meeting, the minutes of the last Annual General Meeting, and of the subsequent Special General Meeting, were read and signed. The Chairman then nominated Mr. C. Stuart-Walker and Mr. Purling as Scrutineers, and declared the ballot open.

The Secretary then read the

ANNUAL REPORT OF THE COUNCIL.

The Council, as required by the bye-laws, now lay before the members at the Annual General Meeting the report of the proceedings of the past year.

CANTOR LECTURES.

These Lectures, which were tried with so much success last session, have been renewed in the present year. Three courses were selected, bearing on the objects of the Society, namely:—

"On the Reproduction of Natural Forms by Art and Manufacture." Five Lectures, by B. Waterhouse Hawkins, Esq., F.G.S., F.L.S.

"On the Application of Geology to the Arts and Manufactures." Six Lectures, by Professor J. T. Ansted, M.A., F.R.S.

"On the Application of Chemistry to the Arts and Manufactures." Six Lectures, by Dr. F. Race Calvert, F.R.S. Abstracts of the first two courses of these lectures have already appeared in the Society's *Journal*, and full re-

ports of Dr. Calvert's lectures, carefully revised by himself, will shortly be published.

The interest taken in these lectures has in no way diminished, as is abundantly testified by the increasing numbers attending them, even though it was found necessary to curtail the privilege of members to the admission of one friend instead of two, as was the case last year. While this interest continues to be maintained, the Council feel that they cannot do better than make arrangements for carrying on in the next session this branch of the Society's work. In the selection of the subjects and the lecturers it will be the endeavour of the Council to bring before the members of the Society information with regard to Arts and Manufactures which will tend to diffuse a love of Art, and promote a spirit of inquiry among those interested in the numerous industries of the country.

MEDALS AND PRIZES.

The success attendant on the offer of the Art-Workmanship Prizes of last year, induced the Council to renew the competition on a larger scale. Money prizes to the extent of upwards of £500 were offered for competition among the art-workmen of the kingdom, in eighteen different branches of manufacture, and in wood carving. The particulars have already appeared in the *Journal*. Eighty-seven different works were sent in in competition, and were exhibited in the Society's rooms for a few weeks at Christmas. The Council were fortunate enough to secure the services of Messrs. R. Redgrave, R.A., M. Digby Wyatt, and John Webb as adjudicators; and prizes to the extent of £274 were awarded to 37 competitors.

A large meeting of Art-workmen was held in the Society's rooms, by invitation from the Council, with the view of conferring with the workmen themselves upon the system of Art-workmanship competitions instituted by the Society, and receiving suggestions for carrying

them out more effectually. On this occasion it was stated that a larger number of competitors would have come forward had it not been that the workmen in all branches of manufactures had been unusually occupied in their various employments, and thus but little time was left at their own disposal to devote to these works after their hours of labour. At the meeting above alluded to there was strong and unanimous evidence afforded on all sides that the course the Society was pursuing was right, and the Council, acting upon that opinion, have this year renewed the competition on a still more extended scale; prizes are now offered to the amount of above £600, the articles to be sent in to the Society's house in December next.

Looking at the objects for which the various ancient Companies in the City of London were established, the Council thought it right to seek their co-operation in carrying out this scheme for the improvement of the Arts and Manufactures of the United Kingdom. The Worshipful Company of Salters at once placed an annual sum of £10 at the disposal of the Council to be applied in such way as they might think best for promoting the object in view; and the Worshipful Company of Plasterers within the last few days, with a desire to benefit the Art which they represent, have placed at the disposal of the Council one prize of £10, and a second prize of £5, for modelling, to be awarded by the Society under the same conditions as the other Art-workmanship Prizes. The Council have taken steps for making the competition known as widely as possible among workmen, not only in the metropolis but in the great centres of industry of the kingdom, such as Birmingham, Sheffield, the Potteries, &c. It is confidently expected that as the scheme becomes more generally known the response by competitors will increase from year to year, and that at Christmas next the members may expect to see a large number of works exhibited.

For the papers read during the Session medals have been respectively awarded to Mr. J. C. Morton, for his paper "On London Sewage, from an agricultural point of view;" to Mr. W. Stones, for his paper "On Colonisation, its aspects and results;" and to Professor John Coleman, for his paper "On Food for Cattle."

The Albert Gold Medal, founded as a memorial of His Royal Highness the late President of the Society, has been awarded to His Imperial Majesty the Emperor of the French for distinguished merit in promoting in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports

in favour of British subjects. His Royal Highness the President has himself communicated this decision to the Emperor, by whom it has been most graciously received.

Sir W. C. Trevelyan's Prize of £70 for a method of preserving meat, has not yet been awarded. This subject is one of great importance. It is attracting much attention at the present time, and a number of processes, founded on various scientific principles, are being practically put into operation. Some of them have been before the Society, and hold out promise of good results, but hitherto the specimens have not been subjected to a sufficiently lengthened test to warrant the prize being awarded in favour of any one process.

DWELLINGS FOR THE LABOURING CLASS

This subject, it will be remembered, occupied the attention of a Conference in May last year, invited by the Council to discuss it in all its bearings. That Conference lasted two days, was well attended, and after passing a series of resolutions embodying its views, recommended that the matter should be placed in the hands of a committee, who should endeavour to deal with it in a practical manner so far as was possible. Accordingly the Council, on the commencement of the past session, appointed a committee, presided over by the Chairman of the Council, and consisting of a number of gentlemen well known for the interest they have taken in the subject, and practically acquainted with it in all its bearings, both in town and country. This committee has held many meetings, all well attended, and has obtained much statistical and other information bearing on the question. They also visited, in company with Alderman Waterhouse, the various improved dwellings which have lately been built, and are still building, in the metropolis. At their first meeting they divided their discussions into the following heads:—

1. The causes which appear to retard the erection of proper house accommodation, and the improvement of existing houses, for the working classes in town and country.
2. The operation of imperial and local taxation on such dwellings; and the expediency of relieving them from all or a portion of such taxation.
3. The effect of the law of settlement and removal of the poor upon such buildings in country districts.
4. The probable effect of extending the area of local taxation in town and country.
5. The operation of the laws relating to the transfer of real property in small plots, and the conveyance of chambers and suites of rooms.
6. The operation of the destruction of houses by railways and other local improvements.
7. The desirability of facilitating the conveyance of labourers to and from their works by railway.
8. Whether the provisions contained in the existing Acts of Parliament, for granting loans for the improvement of estates, might not be extended to the building of cottages, and if so under what special conditions.
9. Whether the provisions of the common law relating to

house act, and other statutes relating to the public health might not be advantageously extended.

10. Whether there are any other means by which the legislature can promote the object in view.

The Committee in May last presented their report. It appeared from reliable evidence brought before them that the great cause which retarded the erection of good and improved dwellings for the labouring classes was, that they were not commercially remunerative, and therefore would not attract capital to be expended on their construction, though they might pay a per centage on their outlay equal to the ordinary rate of interest on investments, and which might satisfy the philanthropist.

As regards the burdens which have been generally supposed to press heavily on this class of property, the Committee, after investigating the accounts of a considerable number of dwellings of this character found that the total amount of taxation from all sources does not exceed $1\frac{1}{2}$ per cent. on the whole capital invested, an amount which (even if the exemption from the whole of such taxation were practicable) is too small to exercise any appreciable influence on those contemplating the investment of capital in an undertaking of this nature. Under these circumstances, and considering the violation of sound principles involved in making any exemption in favour of any particular class of house property, the Committee did not feel justified in proposing the adoption of any measure of exemption.

The house duty may be usually avoided in blocks of buildings whose size would otherwise make them liable to it, by giving to each set of apartments a door opening to the external air, and making them thereby a distinct tenement.

The Committee recognise the importance of Union rating as affecting materially the erection of cottages in the country, as well as of Mr. Villiers' Act for enlarging the area of settlement. It did not appear that this question would have any material bearing on such dwellings in the metropolis. The law of real property, as affecting the purchase, sale, and transfer of property of this kind, was taken into consideration, and the Committee agreed in the expediency of greater facilities being given by law both for acquiring sites and for transfer from owner to owner. The Exchequer Loan Commissioners have power now, under the Enclosure Acts, to advance money under certain conditions to landowners for the building of cottages on estates in the country, but it does not appear that such loans can be made to aid in the erection of town dwellings, and the Committee are of opinion that facilities should be given for this being done. The demolition of dwellings by railways occupied the attention of the Committee, and they arrived at the conclusion that where public companies, under compulsory powers, destroy houses inhabited by the working classes, they

ought to be compelled to provide sufficient improved dwellings within a convenient distance for the same classes in place of those destroyed, and should have special powers given them for that purpose; the Committee expressed their decided opinion that it would be for the benefit of the community at large that all the metropolitan railway companies should provide cheap means of transit, at convenient times, for labourers; but they hesitated to recommend that this should be made compulsory in all cases, believing that if their views of the results likely to arise from such accommodation to the working classes were correct, the directors of the railway companies would not fail to adopt them.

The importance of further powers being given to enforce sanitary regulations on the owners and inhabitants of this class of property was pointed out by the Committee, and they recommend that a concise analysis of the sanitary laws should be prepared, and that the defects of the existing enactments should be printed and circulated. In this way the attention of men of education and intelligence would be called to the subject, and they might be induced to take part in sanitary work in the neighbourhood in which they reside or carry on business.

The Committee conclude their report by making the following recommendations to the Council:—

1. That corporations, limited owners, &c., should have increased power to sell land for the erection of dwellings for labourers, under conditions as to proper drainage, ventilation, and sanitary regulations.

2. That the public loan commissioners should be authorised to lend money, at a rate not exceeding $\frac{1}{2}$ per cent. per annum, for building dwellings for the labouring classes, under suitable guarantees and with due regard to sanitary arrangements.

3. That in all future railway acts, and acts for local improvements, when houses inhabited by the working classes are destroyed under compulsory powers, such companies should be compelled to provide, within a convenient distance, other dwellings in lieu of those destroyed.

That the following amendments should be made in our sanitary laws:—

a. That the appointment of inspectors of nuisances throughout the country should be compulsory.

b. That increased power be given to the proper local authorities, to oblige builders of houses to provide adequate drainage and ventilation.

c. That the medical officers of health should be irremovable without the consent of the Privy Council, and that the amount of their salaries should be subject to the approval of the same authority.

d. That houses in which lodgers are taken, especially where particular rooms in a house are overcrowded, should be brought under more efficient inspection.

5. That with the view of extending an accurate knowledge of the powers contained in the various acts relating to the removal of nuisances, the Council is recommended to prepare and publish a concise analysis of the existing law, calling the attention of the educated classes to this important subject, and pointing out how they may, merely by a little attention and exertion, confer most important benefits upon a large mass of working people and upon the country generally.

The Council are now taking steps for getting these recommendations carried into effect, and in reply to their application made to Her Majesty's Government have received a communication from the Lords of the Treasury that their lordships are willing and intend to apply to Parliament for power to enable them to grant loans of public money for the erection of dwellings for the labouring classes on condition that the public bodies undertaking their erection limit their rate of profit to £5 per cent., so as to distinguish their case from that of ordinary commercial enterprise. The details of the report have already been printed in the *Journal*.

MUSICAL EDUCATION.

A committee has been appointed to consider the condition of musical education in this country and abroad, and His Royal Highness the President honoured the Committee by consenting to accept the chairmanship of it, and proposes to give the subject his attention when the evidence is laid before him. The committee has already held several sittings, and has taken the evidence of several eminent men in this branch of the Fine Arts. With the aid of the Government, through the agency of Her Majesty's Ministers in foreign countries, information of an extremely useful character has been received in reference to the musical establishments in the leading continental cities. It is intended to print this information, as well as the evidence given before the committee, in the *Journal*. The Council believe it will be of interest to the members, and have hopes that, through the influence of the Society, measures for promoting Musical Education may be adopted in this country as effective as those in Paris and other Continental cities.

UNION OF INSTITUTIONS.

The Secretary's report, read to the Conference of representatives of Institutions held on the 14th inst., shows the position of this branch of the Society's operations. By this it appears that there is no diminution of candidates, the numbers attending the Examinations of the Society increasing from year to year.

FINANCE.

The accounts, showing the financial position of the Society, were published, as directed by the bye-laws, in the *Journal* of last week. By these it appears that the extraordinary liabilities at the close of the last year have all been discharged. Thus it will be seen that the heavy expenditure due to the renewal of the Society's lease, the alterations and repairs of the premises, and the publication of the Jury Reports, amounting to above £6,000, have been discharged out of the income of the Society, with the exception of £545 borrowed of the memorial fund, and the sale of stock to the value of

£1,600; while the ordinary liabilities of the Society in current accounts remain as usual. The number of members continues steadily to increase.

The Treasurers' statement of receipts, payments, and expenditure for the year ending 31st May, 1865, as published in the *Journal* last week, was read by the Secretary.

The CHAIRMAN asked whether any member present required any further information, or wished to offer any observations either upon the accounts or on the general proceedings of the Society, on which

Mr. T. H. HARTLEY said, that early in the Session he called the attention of the Society to the subject of the scarcity of skilled labour in this country. The importance of that question was becoming more and more apparent from the great inconvenience which manufacturers were put to, and he thought it was a matter which should be discussed by the Society, and with that view he had sent a communication to the Society for the consideration of the Council. It was evident that unless some means were taken to a greater extent than had yet been done to train the youth of this country to skilled occupations, our manufacturers would be obliged to depend mainly upon foreigners. It was the case that in his own branch of business—the working of marble—he was obliged to depend a good deal upon foreign workmen, from the great scarcity of native skilled labour. At the same time there were great numbers of youths now confined in prisons and reformatories, who, if turned out from thence as skilled workmen, would be of great service to the state, instead of being a constant burden upon it. He was not aware of any society which was so well adapted to take up this question as the Society of Arts, being one cognate to its objects in the encouragement of arts and manufactures. The present state of the law with regard to apprentices was such as to discourage masters from taking them, and thus the great source of supply of skilled labour was, to a considerable extent, cut off. There was no other means of continuing that supply except by training the youth of the country, so as to replace the skilled workmen who died off. Another effect of the present state of things was that business suffered and wages were increased to an enormous extent. He always desired to see the workman well paid, but he had no doubt that if things went on in their present course wages would soon rise to 10s. per day. He begged to press this subject upon the attention of the Council. The training of workmen was carried to the greatest extent on the Continent. In Denmark, Sweden, and Prussia, it was made compulsory that youths of a certain age should be apprenticed to some branch of skilled labour; and those countries were now manufacturing very largely avowedly for the supply of the English market. He was himself taking a large number of apprentices, notwithstanding the trouble this involved, and he had established a "home" for them, where as many were housed as the place would accommodate. He had also encouraged, as far as possible, the system of out-door apprenticeship, and he felt confident, if it were properly carried out on a larger scale, it would add greatly to the wealth of the nation in the supply of skilled labour applicable to the various branches of manufacture.

Mr. HENRY COLE, C.B., said he believed he might say on behalf of himself and his colleagues in the Council that they would be happy to place an evening at Mr. Hartley's disposal next session for the reading of a paper on this subject if he would be good enough to prepare one, and he had no doubt the matter would then be fully discussed by the Society. The question of skilled labour was an important one, but for his own part he had no dread of workmen getting 10s. a day. With respect to

the Council's report, he hoped it would be considered satisfactory. It was not for the Council to speak in praise of themselves, but he felt that during the past year—thanks especially to the chairman who had acted during that period—they had brought forward one subject in particular of the highest importance to the welfare of this country. They lived in hopes that the legislature would do what lay in its power to enable the labouring classes of the kingdom to be properly housed. He thought the measure to enlarge the area of rating introduced by Mr. Villiers had a most important bearing upon this question, and he hoped this Society would not let the subject drop. One other point in the report he would also touch upon—that of Musical Education. He lived in great hopes that it would not be very long before England would be able to do for musical education what even the Neapolitans did, and what was done in Paris, Brussels, and in most of the large continental cities. This was a subject which it was hardly to be expected the House of Commons would very readily take up and grant a committee upon; the Council, therefore, thought it quite within the province of the Society to appoint a committee on the subject, regarding music, as indeed it had been regarded from time immemorial, as a most important branch of the fine arts. It was satisfactory to know that his Royal Highness the President took a personal interest in this question; and he (Mr. Cole) had no doubt some good would result from this discussion. He would now move that the report and statement of accounts now presented be received and adopted.

Mr. SEYMOUR TEULON had great pleasure in seconding the motion, and, in doing so, begged, as one of the auditors, to bear his testimony to the very admirable manner in which the accounts were kept by the Financial Officer.

Mr. SYMONS wished to know whether the new catalogue of the library had been completed, and, if so, whether it was intended to print it.

The SECRETARY replied that the manuscript copy had been completed for some time, and was available for the use of the members. It had not been thought advisable to go to the expense of printing it.

Mr. COLE quite agreed in the undesirableness of printing the catalogue, inasmuch as in any large library a printed catalogue, though perfect to-day, would be imperfect to-morrow. The fashion of printing catalogues of large libraries was now quite exploded.

Mr. SYMONS remarked that from a cursory view of the accounts it appeared to him that the Society was £1,000 out of pocket during the last year, which he thought would probably be accounted for by the exceptional items of the printing of the Jury Reports and the repairs of the building.

The CHAIRMAN explained that the two heavy items of the Jury Reports of the Exhibition of 1862, and the expenses incidental to the renewal of the lease, and the consequent repair of the premises (amounting to about £2,400) had been discharged without trenching upon the capital to the extent of more than £1,600, showing that, at any rate, they had been spending less than their income in their ordinary expenses.

The report was then unanimously adopted.

The ballot having remained open one hour, and the scrutineers having reported, the Chairman declared that the following members had been elected to fill the several offices. The names in *italics* are those of members who have not during the past year filled the offices to which they have been elected:—

COUNCIL.

PRESIDENT.

H.R.H. the Prince of Wales, K.G.

VICE-PRESIDENTS.

Sir Wm. G. Armstrong.
Thomas Baring, M.P.
 Lord Berners.
 W. H. Bodkin.
Sir J. P. Boileau, Bart.
 The Earl of Caithness.
 Harry Chester.
 Henry Cole, C.B.
 The Earl Granville, K.G.,
 F.R.S.
Edward Hamilton.
 William Hawes.

C. Wren Hoskyns.
 Lord Henry Lennox, M.P.
 Lord Lyttelton.
 Right Hon. Sir John S.
 Pakington, Bart., M.P.
 Sir Thomas Phillips, F.G.S.
 The Marquis of Salisbury,
 K.G.
 The Duke of Sutherland.
 Thomas Twining.
 Vice-Chancellor Sir William
 Page Wood, F.R.S.

COUNCIL.

Professor Bentley.
 D. Robertson Blaine.
Stephen Cave, M.P.
 John Bailey Denton.
 Peter Graham.
Henry Maudslay.

Samuel Redgrave.
Rev. W. Rogers.
 Sir Francis Sandford.
Col. Scott, R.E.
 Geo. F. Wilson, F.R.S.
 Thomas Winkworth.

TREASURERS.

W. B. Simpson.

| Seymour Teulon.

AUDITORS.

H. Reader Lack.

| Philip Wright.

SECRETARY.

Peter Le Neve Foster, M.A.

FINANCIAL OFFICER.

Samuel Thomas Davenport.

At the conclusion of the General Meeting a Special Meeting was held, when the following candidates were balloted for and duly elected members of the Society:—

Attwood, J., 61, Cannon-street, E.C.
 Auld, Thomas Reid, 36, Portland-place, W.
 Bruce, James, Inverquhomery, Longside, Aberdeenshire.
 Crawford, Peachey Sowerby, 117, Lupus-street, S.W.
 Graham, William F., Woodberry Down, Stoke Newington, N.
 Green, Squire, 4, Shrewsbury-cottages, Holland-road, Brixton, S.
 Hawkins, Henry, Wallingford, Berkshire.
 Holroyd, Edward, Church-street, Wimbledon, S.W.
 Miller, James Gordon, Financial Insurance Company, 60, King William-street, E.C.
 Moseley, Walker, 17 and 18, King-street, Covent-garden, W.C.
 Payne, Wyndham, 32, Kensington-square, W.
 Roper-Curzon, Hon. Sidney, Grove House, Lower Tooting, S.
 Scarell, Thomas, Beddgelert, Carnarvonshire.
 Sims, Frederic John, Colemore-row, Birmingham.
 Smith, Thomas Roger, 57, Strand, W.C.
 Trotman, John, 42, Cornhill, E.C., and 31, Acacia-road, N.W.
 Walmisley, John Richard Lambert, 5, Victoria-street, Westminster Abbey, S.W.
 Webb, Capt. Sydney, 24, Manchester-square, W.
 Westfield, George John, 5, King-street, Finsbury, E.C.

Mr. SEYMOUR TEULON said this being the last meeting of the Session he thought that, considering the very efficient manner in which the Chairman had discharged the laborious duties of his office, they ought not to separate without passing a cordial vote of thanks to that gentleman for his constant attention to the business of the Society, and for the ability and zeal with which he had presided on so many occasions over their meetings during the past year.

Mr. BARKER had great pleasure in seconding the motion. For some months past he could himself bear testimony to the indefatigable manner in which Mr. Hawes had discharged his duties, not only in this room, but also in connection with the Committee on Labourers' Dwellings, of which he (Mr. Barker) was a member. They were greatly indebted to him for the time he had devoted to the interests of the Society, and for the manner in which he had discharged all the duties connected with his important position.

The motion was carried unanimously, and the Chairman acknowledged the compliment paid to him.

A vote of thanks to the scrutineers terminated the proceedings.

EXAMINATION PAPERS, 1865.

The following are the Examination Papers set in the various subjects at the Society's Final Examinations, held in April last:—

ARITHMETIC.

THREE HOURS ALLOWED.

- Find, by Practice, the value of 835½ articles at £2 18s. 4d. each.
- The price of iron is 16s. 7½d. per cwt., find the cost of 24 tons, 15 cwt., 2 qrs., 14 lbs.
- Find the sum, in integers, of £8125, 4875s., and 75d.
- If 2,240 stones, each 9 in. square, will pave a yard, how many stones will be required to pave a yard twice the size, each stone measuring 14 in. by 12?
- Convert £540 17s. 6d. into decimal currency, £1 being the unit, and then find its simple interest for 3½ years at 4 per cent. per annum, expressing the answer both in decimal and ordinary currency.
- Goods were sold for £225 10s. with a gain of 12½ per cent.; what would have been gained or lost per cent. by selling them for £187 10s.? Work by decimal currency.
- A workman's wages are 1 flor. 3 cents, 4 mile a day, and his expenses are 12s. 6d. a week; what will his savings amount to at the end of a year in common money?
- Exchange into English decimal coinage 12,687 francs, 50 centimes, the rate of exchange being 25 francs 32½ centimes per pound sterling.
- If a person whose income is £865 a year spend £8 16s. 3d. a week for the first 20 weeks, to what amount must he limit his daily expenditure for the remainder of the year so as to avoid being in debt at the end of it?
- Find the insurance at 8 per cent. on a house worth £874, so that in case of fire the insurer may receive the value of the house and premium.
- Transfer £1,500 of 8 per cent. stock at 90 to the 4 per cents. at 75, and find the difference in the annual income.
- A merchant bought 24 cwt. of sugar at 5½d. per lb., and sold ½ of it at 6½d., ¼ of it at 6d., and the remainder at 5½d. per lb., what is his gain per cent.?
- A tradesman marks his goods with two prices, one for ready money and the other for a year's credit, allowing discount at 5 per cent.; if the credit price is £2 8s., what ought the cash price to be?
- A has goods worth 30s. which he barter with B at 45s., allowing him 9 months' credit; B rates his exchange at 20s., giving six months' credit. What is the value of B's goods?
- At a game of skill A can give B 10 points out of 50, and B can give C 10 points out of 60. How many points can A afford to give C out of 50?
- If oranges can be bought at the rate of 20 a shilling, how many should be sold for £1 8s. to gain 40 per cent.?

17. A, B, and C are partners, A receiving ⅓ of the profits, B and C sharing the remainder equally. A's income is increased £220 when the profits rise from 8 to 10 per cent. Find the respective capitals invested.

18. A merchant purchases wheat at 71s. 6d. a quarter; at what must he sell it to gain 12½ per cent. and allow a purchaser 2½ per cent. discount?

19. What half-yearly dividend is due upon an investment of £2,500 in the Three per Cents at 87½ after deducting 7d. in the pound for income-tax?

20. If 15 men be necessary to excavate 966 cubic yards in 8 days, working 10½ hours daily, how many men would be required to excavate 575 cubic yards in 12 days working 7½ hours daily, 4 extra men being taken on during the last 4 days?

BOOK-KEEPING BY DOUBLE ENTRY.

THREE HOURS ALLOWED.

- In what does the difference between single entry and double entry consist, and what is the special advantage possessed by the double entry method?
- What is the distinctive use of the "Journal" in the Italian system of book-keeping by double entry?
- What should a profit and loss account exhibit?
- What should a balance sheet exhibit?
- Journalize and post in proper technical form in language, the following imaginary facts and transactions, and make out from the ledger, a trial balance, a profit and loss account, and a balance sheet.

John Long and James Rose begin business in partnership on the 1st January, 1865.

John Long's capital was £2,000 in cash, and James Rose's capital £1,500 in cash and £1,000 in wine.

N.B.—The capital and drawings of the partners are subject to interest at 5 per cent. per annum, and the balance of the profit and loss account is divisible thus:—To John Long one-third, to James Rose two-thirds.

1865.

Jan. 3. Bought of Tom Styles, wine, duty paid	£450 0 0
" Accepted Tom Styles draft @ two months date	450 0 0
5. Lent John Nokes cash	300 0 0
7. Sold to W. Box, wine	800 0 0
" Sold to H. Potts, wine	250 0 0
" Received of W. Box, cash on account	600 0 0
8. Sold to S. Vix, wine	120 0 0
" Paid cash for office furniture and fixtures	105 0 0
9. Received of W. Box, his acceptance @ six months	205 0 0
" Charge W. Box with interest, six months, on £200	5 0 0
12. Shipped on own account and risk to Bombay, wine invoiced at	330 0 0
13. Bought wine of J. Styles	700 0 0
" Paid cash to J. Styles on account ...	600 0 0
15. Cash drawn out by James Rose	400 0 0
" Do. do. by John Long	100 0 0
" Bought of C. Aggs, wine	630 0 0
16. Received cash, advance on the above shipment to Bombay	140 0 0
" Bought wine for ready money, and paid cash	1,150 0 0
" Accepted C. Aggs draft at three months date	500 0 0
Jan. 18. Sold wine to J. Nokes	£225 0 0
" Charge interest to J. Nokes	7 10 0
" Received of J. Nokes his acceptance on account	722 10 0
" Advanced for petty cash	20 0 0
20. Sold wine to J. Nokes	270 0 0
" " " J. Dodd	260 0 0
23. " " " B. Kell	400 0 0
" Paid trade charges out of petty cash	8 6 0

24. Bought wine of N. Scott	125	0	0
26. Received of J. Nokes his acceptances	100	0	0
" S. Dodd	300	0	0
28. Discounted with O. G. & Co. J. Nokes' acceptance for	732	10	0
" Received cash of O. G. & Co.	705	5	0
" Discount charged by O. G. & Co. ...	27	5	0
30. Paid to N. Scott, W. Box's acceptance	205	0	0
31. Stock of wine on hand at cost	950	0	0
" Interest on amount drawn out by John Long	0	8	4
" Interest on John Long's capital	8	6	6
" Interest on amount drawn out by James Rose	0	13	4
" Interest on James Rose's capital	10	8	4
" Rent due to A. Bone	18	10	0
" Salary due to T. Fox	25	0	0
" Trade charges paid out of petty cash	9	8	0

ALGEBRA.

THREE HOURS ALLOWED.

A.

1. If n is any integer, show that $x^n - a^n$ will divide out by $x - a$, and find the value of the quotient.
2. If $A_n - A_{n-1} + A_{n-2} + \dots + A_1 + A_0 = 0$ prove that $A_n x^n + A_{n-1} x^{n-1} + \dots + A_1 x + A_0$ contains the factor $x - a$.
3. Find the value of the continued product of $a + b + c$; $a + b - c$; $a - b + c$; $a - b - c$; and account for the result remaining unchanged when any two letters in it are interchanged, and also for it containing no odd power of a , b , or c .

$$\frac{a+b}{c+d} + \frac{a-b}{c-d}$$

4. Reduce the fraction $\frac{a+b}{c+d} + \frac{a-b}{c-d}$ to its simplest form.

5. The provisions of a fort ran out in 30 weeks; it was originally victualled for 60 weeks, but at the end of eight weeks its strength was doubled, and six weeks later 750, fresh men were thrown in. How many men were in the fort at first?

6. Find the square of $\sqrt{1+c} + \sqrt{1-c}$ and extract the square root of $1 - (1 - c^2)^{\frac{1}{2}}$.

7. If $a + b$, $a + c$, $b + c$, are in harmonic progression, show that a^2 , b^2 , c^2 are in arithmetical progression.

$$\left\{ \begin{array}{l} \frac{x^2}{y} + \frac{y^2}{x} = 18 \\ x + y = 12 \end{array} \right.$$

B.

9. Express 1865 in the ternary scale of notation. Also in a scale employing only the symbols of zero and plus or minus unity (denoted by 1, $\bar{1}$ respectively), express the value of 50.

10. Extract the cube root of 990 in ascending powers of $\frac{1}{100}$ by the binomial theorem, and apply your result to find its value to seven places of decimals.

11. Five sets of three-volumed novels are arranged along a book-shelf; in how many different ways can they be intermixed, taking care that the second volume of any one set is always to be found between the first and last volumes of the same set.

GEOMETRY.

THREE HOURS ALLOWED.

To obtain a First-class Certificate, at least six problems and four propositions must be correctly done; to obtain a Second-class, at least four problems and eight propositions.

1. All the angles made by any number of lines meeting in one point are together equal to four right angles.

2. If two triangles have two sides of the one equal to two sides of the other, each to each, but the angle contained by the two sides of one of them greater than the angle contained by the two sides equal to them of the other, the base of that which has the greater angle shall be greater than the base of the other.

3. Describe a parallelogram that shall be equal to a given triangle, and have one of its angles equal to a given rectilineal angle.

4. If a straight line be bisected and produced to any point, the rectangle contained by the whole line thus produced, and the part of it produced, together with the square on half the line bisected, is equal to the square on the straight line which is made up of the half and the part produced.

5. Draw a straight line from a given point either without or in the circumference, which shall touch a given circle.

6. In a circle the angle in a semi-circle is a right angle; and the angle in a segment, greater than a semi-circle, is less than a right angle; and the angle in a segment less than a semi-circle is greater than a right angle.

7. Describe a circle about a given square.

8. If the sides of two triangles about each of their angles be proportionals, the triangles shall be equiangular to one another, and shall have those angles equal which are opposite to the homologous sides.

9. Similar polygons may be divided into the same number of similar triangles, having the same ratio to one another that the polygons have.

10. If the vertical angle of a triangle be bisected by a straight line which also cuts the base, the rectangle contained by the sides of the triangle is equal to the rectangle contained by the segments of the base together with the square of the line which bisects the angle.

11. If two straight lines be at right angles to the same plane they shall be parallel to one another.

12. If two parallel planes be cut by another plane their common sections with it are parallel.

PROBLEMS.

1. Construct a right-angled triangle, having given the perimeter and one angle.

2. Bisect a given quadrilateral by a straight line drawn through a given angular point.

3. In any quadrilateral the squares on the diagonals are together equal to twice the sum of the squares on the straight lines joining the middle points of opposite sides.

4. Circles are drawn touching a fixed straight line at a fixed point; show that the tangents at the points where they cut a parallel fixed line, all touch a fixed circle.

5. Given one angle of a triangle, the side opposite to it, and the sum of the other two sides—construct the triangle.

6. Divide a given arc of a circle into two parts, so that the chords of these parts shall be to each other in a given ratio.

7. Trisect a given triangle by lines drawn from a given point in one of its sides.

8. Describe a circle which shall touch a given straight line at a given point, and bisect the circumference of a given circle.

9. Point out how, with a card and pair of scissors, ocular proof may be given of any of these propositions:—

- (1) The angles of a triangle are together equal to two right angles.
- (2) Parallelograms upon the same base, and between the same parallels, are equal to one another.
- (3) The squares on the sides containing the right angle of a right-angled triangle are equal to the square on the other side.
- (4) If a straight line be divided into two equal and also into unequal parts, the squares on

the two unequal parts are together double of the square on half the line, and of the square on the line between the points of section.

(To be continued.)

MUSICAL EDUCATION.

In a recent number of the *Journal of the Musical Union*, Mr. Ella makes the following remarks:—

We would strongly recommend an hour's perusal of a very small volume by Fétis, entitled *Musique mise à la portée de tout le monde*, in which he would find that music is more distinctly both an art and a science, than any other of the fine arts. We have once read, in an English print, that music is not a science! England is the country of liberty, where persons may talk and anonymously write any amount of nonsense; but in France, Germany, or Italy, the arts are better understood, and people are not so easily gulled on such matters.

We earnestly hope that the results of the present committee (the Society of Arts Committee), composed entirely of amateurs, unbiased by professional interests, will be more successful, and lead to some practical benefit to music and musicians. In no country are musical publications, classical works of the great masters—sacred and secular, instrumental and vocal—so cheap as in England, and in no other country is good musical instruction so dear! A modern edition of the Messiah, the whole of Beethoven's and Mozart's Sonatas, Mendelssohn's Songs without Words, Bishop's Glees, and a thick volume of hymns and chorales cost less money than a couple of pianoforte lessons by a first-rate master! In fact, there are lessons given in London at high prices, by second and third rate pianists, who, in Vienna, Milan, Stuttgart, Berlin, Brussels, Munich, and Paris, would be extremely fortunate to obtain half the lowest amount demanded. What is wanted to meet the increasing appetite for good music and for the instruction of youths whose parents are unable to afford them a complete education, is a national academy, with government aid, presided over by an experienced professor of independent means and moral influence, on whose judgment reliance can be placed for the appointment of competent masters in each department. Such a man is to be found in London. Genius belongs exclusively to no country, but talent may be obtained by educating those who are endowed with a natural disposition for music; and we ardently hope that the learned and artistically sympathetic Chancellor of the Exchequer will be able to spare a little of the four millions surplus in aid of the cause of music. A national academy, with one thousand students, well educated, would supply us with competent organists, excellent vocalists, and efficient orchestral and military musicians. As the London mechanic justly observed at the recent meeting in the South Kensington Museum, the competition of foreign schools of gratuitous instruction beats us out of the field. Cold temperaments are found in every country, which neither education nor practice can mould into artistic shape; but a country that has produced poets and dramatists, *nulli secundos*, can assuredly produce musicians? Precocious talents abound in this country, and the reason that these young musicians fail to realise in manhood what they promised in childhood, is simply owing to the want of a cheap and complete education under competent masters, with access to libraries and good practical exhibitions of the art.

What is meant by a complete education includes a knowledge of harmony, counterpoint, composition, instrumentation, musical history, structure and nature of instruments, and the elements of acoustics, requiring, at least, six years studious application. To these acquirements might also be added an acquaintance with modern languages—Italian, French, and German.

ON THE ACTION OF SILICATE AND CARBONATE OF SODA ON COTTON FIBRE.

By F. CRACE CALVERT, F.R.S., F.C.S.

I have lately been engaged in investigating a case of injury to goods, which I hope will prove interesting to chemists and manufacturers, from the novelty of the ascertained chemical facts to which the injury is traceable.

A large quantity of blue-dipped indigo cotton goods, with white reserves, were shipped two or three years ago to South Africa, and when opened, some time after their arrival, were found so unsound as to be quite unsaleable, the cotton fibres being so much injured as to give way upon the slightest strain. The goods were, therefore, returned to this country, and placed in my hands to investigate the cause which had produced this damage.

As a large number of bales were returned without having been opened abroad, an excellent opportunity offered itself for selecting a well-defined series of pieces for experiments, and also for judging of the effects of packing a goods generally, when exposed for a long period to the hot and moist atmosphere of tropical climates.

Firstly, on opening the bales, I observed that the bobbin oil cloth which had been employed to protect the goods from external damp, yielded when subjected to a very slight strain, proving that the texture of the cotton fibre had been injured by the oxidation it had undergone, in consequence of its having been saturated with boiled oil.

Secondly, on examining the goods forming the bales, it was found, in every instance, that the outer folds, including the second, and sometimes the third, were stained and dirty, but this did not extend deeper, the inner folds being perfectly free from stain or mildew. These facts show the importance of returning to this country (where claims are intended to be made upon the manufacturers or packers), entire and unopened bales of goods, instead of a few sample pieces, which cannot show the state of the bales and enable the examiner to speak with certainty as to the cause of injury.

I also ascertained that the rottenness of the fabric could not have been caused by their having been packed in a damp condition, for the hygrometric moisture of a piece in the centre of a bale did not exceed 8.5 per cent. Further, the goods were carefully examined to ascertain if any mildew could be discovered, which would have occurred if the goods had been packed in a damp state, as which would certainly have developed itself more fully in the interior of the bales than nearer the outside. If damp packing had been the cause. What completely removed from my mind all doubt as to the cause, was that, on carefully examining the pieces composing the bales, I found among the injured pieces, some which were quite sound, and on submitting these pieces to analysis, comparatively with those which were injured, the following results were obtained:—

The sound pieces left only from 0.55 to 0.65 of ash, whilst the injured pieces left 8.29 and 8.59 of ash, the composition of which was as follows:—

	No. 1.	No. 2.
Insoluble silica	2.94	3.81
Silica combined with soda.....	2.85	2.53
Soda.....	1.77	1.60
Other salts	1.28	0.65
Sulphate of soda.....		
Chloride of sodium		
Sulphate of lead, &c.....		

8.29 8.59

These analyses show that the pieces had been finished with silicate of soda, which had undergone a partial decomposition; while the pieces which left only a few thousandths of ash were found, on further examination, to have been finished in the ordinary way, viz. with amylaceous substances. This induced me to examine more minutely the goods, to ascertain whether it was the silicate of soda, or to the carbonate of soda, arising

of its decomposition, that the injury sustained was due; and I was further prompted to carry on this investigation on the fact that at the present time the tendency amongst manufacturers is to weight their goods. It is well known that the risk of mildew is considerably increased in proportion to the weight of size; consequently there is a great inducement to use mineral in preference to vegetable substances for that purpose. I, therefore, put that the results now published will warn manufacturers of the risk they run in using mineral size without care and experience. Whilst on this point I may be permitted to give here an insight into the nature of the size often used in Lancashire for sizing the warps of grey cloths, and, therefore, I give a few of the results obtained in my laboratory.

ANALYSES OF VARIOUS CLOTHS.

No. 1.

Mineral matter, principally clay and sulphate of magnesia	5.2
Water in excess	2.8
Starched flour	10.0
Hygrometric moisture	8.0
Warp	74.0
	100.0

No. 2.

Mineral matter, principally sulphates of baryta and magnesia	4.5
Water in excess	2.1
Starched flour	11.3
Hygrometric moisture	8.0
Warp	74.1
	100.0

No. 3.

Mineral matter, principally sulphate of soda and clay	4.8
Water in excess	10.0
Starched flour	4.5
Hygrometric moisture	8.0
Warp	72.7
	100.0

No. 4.

Mineral matter	1.24
Water in excess	1.74
Starched flour	13.02
Hygrometric moisture	8.00
Warp	76.00
	100.00

The above data show that warps are sized with sour size (viz., flour which has been allowed to ferment for several days or weeks) and various mineral matters, to the extent, irrespective of moisture, of about 15 per cent. There can be no doubt that goods thus sized are extremely liable to mildew, owing on the one hand to the use of starched flour, or organic matter, in a state of decay, and on the other to the use of clay, which tenaciously retains moisture, and facilitates cryptogamic vegetation on the goods are packed. I may state, *en passant*, that sulphate of magnesia, sulphate of lime, sulphate of baryta, sulphate of soda, and the chlorides of sodium and magnesium are often used, with or without clay, as weighting materials.

In examining the comparative strength of various pieces composing a bale, I observed that the outside folds of the cloths which formed the external parts of the bale (above alluded to as dirty and stained) were comparatively strong when tested against the folds of the same piece which were towards the interior of the bale. I therefore took a same weight of cloth from both classes of folds and submitted them to analysis, with the following results:—

	Interior of bale.	Exterior of bale.
Insoluble silica	4.81	7.08
Silica combined with soda ...	2.53	0.20
Soda	1.60	0.47
Other salts	0.65	0.55
	8.59	8.30

On examining and comparing these figures, it is at once seen that the stained fold shows a large increase in the amount of insoluble silica, and a corresponding decrease in the amount of silica combined with soda; but, notwithstanding this, the total amount of silica is nearly the same in both classes of cloths. Further, that there is a total disappearance in the stained fold, of 1.13 per cent., or more than two-thirds of the total amount of soda. From these results it would appear that the silicate of soda, when first applied to the goods, contained the whole of its silica in combination with the soda, and that under the influence of the carbonic acid of the atmosphere, the silicate of soda has been decomposed into insoluble silica and carbonate of soda, thereby giving rise to great increase in bulk; whilst in the goods which were protected from an excess of moisture—as towards the interior of the bales,—and also from the action of carbonic acid, there is only a partial decomposition of the silicate of soda. Mr. Walter Crum has kindly suggested, and I believe the view to be correct, that the cotton fibre has, by its organic nature, a cohesive attraction for silica, which enhances the decomposition of the silicate of soda employed to finish and weight the goods.

From these facts we may assume that there were two destructive influences brought to bear upon the cotton-fibre—1st, that of the increase of bulk resulting from the decomposition of the silicate of soda, giving rise to the formation of free silica and carbonate of soda, which exercised a distending and disintegrating action upon the cellular tissue of the cotton fibre, causing it to burst, and necessarily weakening its tensile strength; 2nd, the direct and destructive action of the free carbonate of soda upon the fibre. The latter appears to be the principal cause of injury, for in the external folds we have a more complete decomposition of the silicate, as shown in the above figures, by the increase in the amount of insoluble silica, and at the same time a decrease of the soda, amounting, as previously stated, to more than two-thirds of the total weight.

We shall now trace more in detail this interesting decomposition of silicate of soda, and endeavour to show what had become of the soda which had disappeared. To attain this object a complete series of specimens were obtained from an entire bale, viz.: 1, a piece which formed the outside and was stained; 2, some of the paper employed in wrapping the goods, which was in immediate contact with the stained cloth; and, 3, some of the flax wrapping placed next to the paper and between the latter and the oil-cloth covering above alluded to. The following are the results yielded by analysis:—

	PIECES OF GOODS.		PAPER WRAPPING.		FLAX WRAPPING.	
	No. 1. Inside fold.	No. 2. Outside fold.	No. 3. In contact.	No. 4. Not in contact.	No. 5. In contact.	No. 6. Not in contact.
Insoluble silica	4.05	5.65	0.02	0.03	0.04	0.01
Silica combined with soda	2.21	0.38	0.09	0.02	0.08	0.03
Soda	1.76	0.25	0.85	0.01	0.29	0.02
Other substances ...	1.96	1.91	15.15	15.28	1.19	1.26
Total ash...	9.98	8.19	16.11	15.34	1.58	1.31

In examining these results we have again a most striking and marked difference in the amount of insoluble silica

and soluble silicate of soda in the two different parts of the same cloth; and, further, where the carbonate of soda has been removed, the folds of the cloth remain comparatively sound. As to the paper wrapping, it is evident that the paper in contact with the goods has absorbed a great part of the soda which was previously combined with the silica, and that the soda is partly in the state of carbonate, and partly in combination with some of the organic matter of the brown paper; for when some of the paper was treated with water, it yielded a yellowish brown substance, which coloured the liquid, whilst the part of the same paper which had not been in contact with the goods did not discolour water in any marked degree. Further, the aqueous solution was neutral, and not alkaline, as in the previous case. As to the flax wrapping, the same difference as noted in the paper was observed, viz., that the part of the wrapping in contact with the stained paper and the stained fabric contained carbonate of soda, whilst that which was in contact with the clean paper contained only a trace. In looking over the bales, a piece of cloth was found, which had been finished with silicate of soda, and was partly overlapped by another piece, showing one-half of its exterior fold stained and comparatively sound, whilst that half of the fold which was prevented from forming the exterior of the bale by being overlapped by the previous one was quite tender and rotten, though it showed no signs of any stains or mildew. I also examined a sound piece which had laid in contact with an injured one, and found that in those folds which had been in contact, there was in the injured piece less soluble silicate, and in the folds of the sound piece a considerable quantity of carbonate of soda, the presence of which could not be found in the folds forming the centre of it.

Having observed that the reserved white patterns of the blue-dipped Indigo cloth were a great deal more tender than the blue portions of the same piece, I carefully cut out a portion of the white parts and submitted them, with the blue parts, to analysis, with the following results:—

	White.	Blue.
Insoluble silica	5.48	3.17
Silica combined with soda...	0.18	2.10
Soda	0.78	1.43
Other salts	1.08	0.67
Total	7.52	7.37

These figures illustrate the fact that the decomposition of the silicate of soda has been carried on to a much greater extent in the white parts than in the blue; and I am led to believe that the cause of the increased rottenness in the white is due to the printer having used a resist-paste too acid, and having found that the whites were slightly tendered, he endeavoured to check the further action of the acid on the cotton-fibre (which, as chemists well know, continues until the cotton fibre is completely destroyed) by the employment of a strong solution of silicate of soda, which, being an alkaline salt, was well adapted to neutralise any acid in the cloth and arrest its action. And as previously only weak solutions of silicate of soda had been employed for this purpose, the printer of these goods could not have foreseen that the use of a more concentrated solution would result in such serious consequences. The above figures also prove another interesting fact, viz., that the white parts of the cloth contain a much larger proportion of silicate of soda than the blues, thus proving that the dyed indigo fibres, being partially filled with this resinous dyeing material, were not in a condition to absorb so largely the silicate of soda.

Messrs. H. Caro and Dancer, who were also employed to investigate this matter, entertain a different opinion as to the cause of the white parts being more injured than the blues. These gentlemen are led to believe from their results that the reason why the whites are more injured than the blues is, that a slow chemical action has ensued between the sulphate of lead remaining from the reserve

paste and the silicate of soda, and that a silicate of lead has been formed, and as this salt occupies a larger bulk than the sulphate of lead previously existing in the fibre, the production of it inside the cellular tissue of the fibre has been the cause of the increased tenderness of the whites. But as these gentlemen are engaged in investigating the question more fully, I shall leave to them the pleasure of publishing their results.

Lastly, I deemed it my duty to make some direct experiments on the action of silicate of soda on cotton fibre. I therefore took some white cotton and dyed a portion of it with indigo. This blue-dyed cloth, with a part of the white one, were dipped in a moderately strong solution of silicate of soda, then dried, and a portion of them introduced into a bottle, at the bottom of which a little water had been placed, and, to help the action of the carbonic acid of the atmosphere, a slow current of carbonic acid was then passed through the bottles containing the cloths. After three months' time the warps of these samples were tested, and their comparative weights were found to be as follows:—

The warps of the unsilicated cloth dyed blue...	On an average 10 days 334
The same silicated	329
	324
	329

These results leave no doubt that the warps, &c. during the short period of three months, had been considerably injured by contact with silicate of soda. In conclusion, I beg to add that I am aware that silicate of soda has been used for finishing coloured goods, but when employed it has been in a very dilute state, and therefore its destructive action has not been sufficiently marked to draw the attention of calico printers.

Fine Arts.

A LADY KNIGHT.—One of the last acts of the Emperor Regent, during the absence of Louis Napoleon in Algeria, was the decoration of the admirable artist, Rosa, or rather Rosalie, Bonheur, who thus becomes *Chevalière* of the Legion of Honour. The cross of the order has not before been conferred upon a woman, with the exception of sisters of charity, members of other religious communities, and *vivandières* who have risked their own lives in performing acts of charity and devotion. Now that the first step has been taken there is little doubt the others will follow. Madame George Sand is by all accounts the first writer, the most accomplished romancer, in France, while Madame Henriette Browne and other ladies hold a very high position in the arts. As regards Rosa Bonheur, it is not, perhaps, generally known that the lady belongs to a family of artists: her brother Auguste, landscapes and cattle are deservedly admired; another and younger brother, Jules Isidore Bonheur, is a sculptor of animals principally, and four of his groups have been rewarded with medals; in the exhibition now open at Paris there are two bulls, modelled by him for the Salons which are extremely fine; lastly, Rosa Bonheur has a sister named Juliette, now Madame Peyrol, who is a painter of still-life, and the two ladies have performed good service in the establishment and superintendence of a free drawing school for girls. Moreover, these fine artists were all children and pupils of Raymond Bonheur, a painter of merit, who died in 1853. It is not odd that the same kind of talent is found thus to enter a whole family.

NATIONAL PORTRAIT EXHIBITION.—The Lords of the Committee of Council on Education have received a letter from the Earl of Derby, suggesting the formation of a National Portrait Exhibition, from which letter the following extracts are made:—"I have long thought that a

National Portrait Exhibition, chronologically arranged, might not only possess great historical interest by bringing together portraits of all the most eminent contemporaries of their respective eras, but might also serve to illustrate the progress and condition, at various periods, of British art. My idea, therefore, would be, to admit either portraits of eminent men, though by inferior or unknown artists, or portraits by eminent artists, though of obscure or unknown individuals. I have, of course, no means of knowing, or estimating, the number of such portraits which may exist in the country; but I am persuaded that, exclusive of the large collections in many great houses, there are very many scattered about by ones and twos and threes in private families, the owners of which, though they could not be persuaded to part with them, would willingly spare them for a few months for a public object." * * "The question of one, two, or three exhibitions in consecutive years, would, I apprehend, be mainly decided by the result of future inquiries as to the probable number of pictures which could be obtained, and the space which could be found for their exhibition. But whether the period over which each exhibition (if more than one) should range, be longer or shorter, the point on which I should set the greatest value, in an historical, if not in an artistic point of view, would be the strict maintenance of the chronological series. I shall be very happy if any suggestion of mine should lead the Committee of Council to take up seriously, and carry out, with such alterations of detail as experience might suggest, a scheme which I think could hardly fail of being generally interesting; and I should have much pleasure in placing temporarily at their disposal any portraits from my collection at Knowley which they might think suitable for their purpose." Their lordships state that they consider these suggestions very valuable, and will carry into effect, in the year 1866, a National Portrait Exhibition generally in accordance with them. They propose to constitute a Committee of Advice, and to invite the Trustees of the National Portrait Gallery to be members of it. Mr. Samuel Redgrave, to whose valuable labours the successful formation of the Collection of Portrait Miniatures is chiefly due, is to be requested to undertake the special charge of carrying this minute into effect.

ARTISTIC EDUCATION IN PARIS.—The Prefect of the Seine appointed a commission, some time since, to inquire into the best means of improving the system of teaching drawing and design in the municipal schools. The commission was presided over by M. Dumas, of the *Institut*, and included amongst its members the Count de Nieuwkerke, superintendent of Fine Arts, M. Viollet Leduc, architect, M. Gérôme, and other artists. It has just published its report, in which great stress is laid on the necessity for extending the practice of the art of design amongst the population of the capital as a powerful element in industrial success. Considering that the true interests of industrial art cannot be separated from those of pure art, the commission decides that strict examinations shall take place in all the public schools of the city. This list includes all the primary schools, the classes for apprentices and adults, as well as all others which receive a libvention from the municipality. The commission declares the present system of teaching elementary art to be too restricted, and considers special professors absolutely required in order to give the pupils precision of eye, hand, and taste; further, that it is necessary to supply the schools with the best models, to establish special courses of instruction for the various branches of industrial art, and to institute competitions amongst the pupils with the view, not only of stimulating the endeavours, but also of sustaining the zeal of the teachers. The application of the same principles in the case of the female classes is declared indispensable, not only with regard to the cultivation of taste and improvement in industry, but also in moral point of view, as opening the way for female occupation in those branches of art which do not require physical force but a delicate and tutored hand. In pursu-

ance of the views of the commission, Count de Nieuwkerke has placed at the disposal of the municipal authorities all the casts and engravings in the Louvre which may be available for Art education in the schools. This is only one instance of the many means that are being brought into operation in France to improve the industrial population, and to maintain for the artistic products of Paris that pre-eminence which in many branches they have so long enjoyed; whilst the large number of artists from amongst which professors and teachers may be secured for the schools gives France, and especially Paris, an immense advantage over most of her neighbours and rivals.

Manufactures.

PLATINUM.—It has lately been asserted in some journals that this metal for the purpose of boiling sulphuric acid is going out of use, owing to being corroded by the hot acid, and that glass is taking its place. It has been further stated that although platinum by itself is affected by the action of this acid, yet that an alloy of platinum and iridium is not acted upon, and that experiments lately instituted have proved these facts. The contrary is really the fact. Platinum is not going out of use, but, on the contrary, is more largely than ever used for this purpose; and where glass has hitherto been used on account of its cheapness it is being replaced by the dearer article platinum, because the latter is found to be more efficient and in the long run less costly. Boilers, after upwards of thirty years' constant work, have been found practically uninjured and as fit for work as the day they were originally put up. As regards the alloy of platinum and iridium being unaffected by the acid, the fact is that it is very readily acted upon, and wherever tried it has failed. Messrs. Crose and Blackwell have lately gone to the expense of a platinum steam coil, made of pure platinum tubing, tested to a steam pressure of 60 lbs. to the square inch, to be used by them in boiling the pickling vinegar. This coil is the first of the kind that has been made. It boils 325 gallons of vinegar (the capacity of the vat) in 1½ hours, with steam at 30lbs. pressure. It is made of pure platinum, autogenously soldered. The length of tubing, 1½ inch diameter, consumed, is 32 feet. It was manufactured by Messrs. Johnson and Matthey, at a cost of £800.

ALUMINIUM.—A use seems still to be wanted for this metal, which possesses so many remarkable qualities. At present it is not so much employed in the arts as its very special qualities would warrant. Messrs. Crose and Blackwell, the well-known manufacturers of pickles and preserves, have lately had made of this material a large boiler, in which their jams and preserves are boiled. By this means all injury from any contact with copper is avoided, and the aluminium is not attacked by the operation.

SILKWORM DISEASE.—The disease amongst the silkworms, known in France by the name of *La Gâtine*, has become so serious in that country as to amount to a great public calamity, and its importance is increased by the fact that Italy, Spain, Greece, Turkey, Asia Minor, and a part of China are all suffering from the same cause in a greater or less degree. The French Government has, during the last few years, made great efforts to help the unfortunate silkworm rearsers and mulberry tree growers, but with little success, and the subject has been brought before the Senate in the form of a report, made by the celebrated chemist and senator, Dumas, on two petitions presented to the chamber. One of the petitions is signed by more than three thousand five hundred maires, municipal councillors, and landed proprietors of the Gard and neighbouring departments, whence comes nearly all the silk produced in France. The account given by the petitioners exhibits a state of things far more serious than

was generally imagined. M. Dumas says, in his report, that it is impossible to doubt that the gravity, duration, mysterious character, and effects of the disease are most lamentable. All evidence shows that it attaches to the worm and not to the mulberry leaves; but the breeders have become so impoverished that they cannot purchase the leaves, and there is great danger that the losses of the mulberry growers will cause the trees to be uprooted to make place for some profitable crop. A striking proof of the extent of the evil is to be found in the fact that the *Crédit foncier* and other financial societies decline to make any more advances on mulberry plantations. The extent of the misery which has thus fallen on the unfortunate farmers and breeders of the basin of the Rhone may be conceived from the fact that nine-tenths of all the silk of France comes from that district. The cocoons produced in the empire were valued on an average at a hundred millions of francs, or four millions sterling per annum, and in 1853 the total rose to nearly a hundred and twenty millions. To produce this amount of cocoons eight tons of silkworms' eggs, or seed, as it is called, and six hundred thousand tons of mulberry leaves are required. The ordinary value of the former is set down at three to four millions, and of the latter at fifty to sixty millions of francs. In 1856 the disease had reduced the crop to one-third of the average, and one-half an ordinary crop is now considered a large yield. The loss of the mulberry growers, M. Dumas thinks, has probably not been far short of thirty millions of francs a year. The disease has attacked worms from all countries indiscriminately, with the single exception of those bred from eggs brought direct from Japan. The supply of these latter eggs has been considerable, but not sufficient to revivify the business, and besides, the price is so high that the poor breeders have not the means of purchasing them. The Japanese seed costs from twelve to twenty francs per ounce, whereas formerly French seed cost only one or two francs, and was frequently given away. The petitions have been referred to the Ministers of Agriculture of the Colonies and of Foreign Affairs, and means will doubtless be taken to afford temporary relief to the suffering agriculturists. As regards the eggs, the only way of bringing them to Europe safely is in the ships almost specially devoted to the service, as the cases require to be opened and examined on the voyage, and the presence of any strong smelling commodities in the ship is said to have an injurious effect.

AGRICULTURAL AND INDUSTRIAL EXHIBITION AT CHAUMONT.—An agricultural exhibition of the products of the north-eastern departments of France has recently taken place at Chaumont, in the Haute Marne, after an interval of seven years. The horned cattle in the exhibition amounted to 320 heads, amongst which those of the Charolaise race were prominent. These animals, being powerful and precocious, are eminently useful for labour, and their flesh is highly esteemed, but the cows give little milk. The department of the Nièvre alone sends 20,000 beasts to Paris yearly. There were a few Durhams and half-breeds in the show, and a very fine collection of Merino and other sheep, the district being noted for its fine wool. An Industrial Exhibition was inaugurated at the same time, and will remain open till the 20th of July. Chaumont and its neighbourhood are famous, amongst other matters, for cutlery—at Nogent there are eight thousand workmen employed in that trade; also for iron-plate, tools and files of all kinds; the tanneries are extensive, and the glove-trade large and flourishing; cotton and woollen-spinning, wax-bleaching and candle-making, distillation and the timber trade are also extensively developed. There is a large collection of the metallurgical products of the Aube, Isère, Loire, Marne, Meuse, Moselle, Haute-Saône, Vosges, and other departments; a great number of agricultural implements; twenty portable steam-engines; and a variety of objects of general industry and industrial art from all parts of France. The Exhibition is established in a park

belonging to the town, and is contained in twelve large pavilions, surrounded by trees, flowers, and statues. Chaumont is rather more than 150 miles from Paris, on the line of the Eastern railway.

Commerce.

PRODUCTIONS OF CORSICA.—The first general exhibition which took place lately in Corsica, has been the means of making the resources of that curious island known for the first time to the French public generally. Within the last twelve years the island has been reclaimed from almost a savage state. In 1840 there was but one main road, and no public conveyances; now there are imperial and eighteen other main roads, making together 1,744 kilometres, or about 1,000 miles. There are steamers five times a week, which place the island within twenty hours' journey of Marseilles. The sheep are still, however, maintain rather uncivilised habits, and do not eat in confinement, so that those shown at the exhibition had to be turned loose during the night. The sheep give no wool, but hair, which is made into coarse stuffs for the peasants' winter wear. The olive, vine, orange, citron, almond, fig, and mulberry, flourish luxuriantly in Corsica. There were no less than 25 exhibitors of oil at the late show; and the value of the crop is set down at nearly £160,000 a year. Corsica sends large quantities of oranges, citrons, almonds, and other fruits fresh and preserved, to Marseilles—the citrons alone amounting to 1,500 tons. The higher mountains are covered with oaks, beech, fir, and other timber trees which attain magnificent dimensions; the middle region produces chestnuts in a profusion that is to be found nowhere else, and their excessive abundance is cited as one of the causes of the inertness of the rural population. The wooded districts all abound with deer, wild boars, muffs, and other game; and the Corsican blackbirds are esteemed a great delicacy, and are shipped by hundreds of thousands from Ajaccio, Bastia, and other parts. The mineral productions of the island are, perhaps, better known; the iron works employ about seventeen hundred men, the abundance of wood and the cheapness of transport offering great facilities for the trade. The extensive deposits of marble, antimony, copper ore, coal, and other minerals, lie unworked for want of capital. Taken together with the cork forests, resinous products, cotton and silk, form the staple of the future prosperity of Corsica, which, in a commercial point of view, must be regarded as almost in a savage state.

FLOATING STOREHOUSES FOR INFLAMMABLE SUBSTANCES.—A slight notice of the new plan of storing dangerous substances, adopted at the new dock and warehouses now being formed at St. Ouen, between Paris and St. Denis was given in the *Journal* of the 9th of December last. We are now enabled, from personal observation, to furnish particulars respecting the new floating magazine. They consist, in fact, of a series of iron cylinders set endways, and strapped together, so as to form a huge compound tubular barge. The cylinders, formed of boiler plate, are each about sixteen feet high, and between six and seven feet in diameter, the tops and bottoms being convex, and the former provided with a man-hole. They are arranged in four rows, of twenty-five in each row, and the whole are covered down to the line of flotation with stout planking, which is attached to the cylinders by means of angle-irons rivetted on the latter. The heads and stern of these huge floating magazines are provided with hauser-holes for the purpose of towing and mooring them in the basins of the docks. In the case of loading and unloading the magazines may be warped to the dock wall, or the liquids may be pumped in and out from barges. Two of these novel storehouses are now afloat, and two more are nearly finished, as regards the iron-work. As to the docks themselves, a fine aqueduct

stone basin, with a surface of 55,000 metres, provided with gates, and also a long and wide canal, are completed, and the iron frame-work of warehouses, six stories high, which will enclose the basin on three sides, is being proceeded with. Immediately in the rear of these three stacks of warehouses are railways, which will bring the latter in direct communication with the Chemin de Fer de Ceinture, which will shortly surround Paris, and which already brings the goods stations of the five great railways in communication with each other.

Colonies.

NEW SOUTH WALES FINANCE.—From the abstract of the sums required to meet the estimated expenditure of the Government of New South Wales for the year 1865, it appears that the total amount chargeable on revenue is £1,494,060 against £1,429,873 appropriated for the year 1864—increase £4,187. The total amount required to be raised by loan, for 1865, is altogether £185,400, against £170,026 for the year 1864. Under the head of special appropriations the amount required for the year 1865 is £391,458, against £341,500 for 1864. This increase of £50,000 is caused by the interest on debentures, which were authorised but only lately issued, and now amounts to £300,000, or £20,000 more than for the year 1864. This will make the debt in debentures actually issued amount to £6,000,000. There is also £16,458 for interest on Treasury bills, and £10,000 for revenue and receipts returned. The total amount required for the year 1865, including loans, is £2,010,918, against £2,441,399 voted for the year 1864.

INDUSTRIES IN NEW SOUTH WALES.—A large timber mill has lately been established on the Goulburn river, and is capable of turning out 18,000 superficial feet of timber per week upon ordinary occasions, but, if pressed, can turn out 25,000 feet. The proprietors have erected a wooden bridge across the Goulburn river, which spans the river 260 feet from bank to bank, by a width of 15 ft., with a roadway of 12 feet. Until this enterprising man had established these works scarcely a woodman's axe had even been lifted in those parts. The timber that is procurable is of a very fine description, and can be produced at almost any length from 5 feet in diameter to 100 ft. in length, but the generality used is from 60 to 70 ft. in length. Mostly all the timber on the river's bank is of a first-class description, being, unlike most of the colonial timber, very sound.

TRADE IN MELBOURNE.—It is stated that a company of Melbourne capitalists intend to place a line of light draught steamers on the Murray to trade between Echuca and the ports up and down the river. These vessels are to draw from 18 to 24 feet of water, and are to be constructed of iron.

Obituary.

FRANÇOIS CLEMENT MOREAU.—A French sculptor, whose admirable statue of Aristophanes obtained a medal, and is one of the most admired productions in the present exhibition of the works of living artists, was carried away very suddenly a few days since by aneurism of the heart. M. Moreau was little over thirty years of age.

Publications Issued.

FOREIGN MEASURES AND THEIR ENGLISH VALUES. By Herbert C. Carrington, F.R.G.S., Hydrographical Draughtsman of the Admiralty. (J. D. Potter, Admiralty Chart Department.)—Contains a systematic arrangement of the measures of all the countries of the world, with their equivalents in English, as well as a detailed explanation

of the metrical system of France, the new decimal systems of Italy, Spain, Portugal, Sweden, &c. The whole work is arranged alphabetically, with a copious index, which also forms a glossary.

ATLAS CELESTE. By Ch. Dien. (Paris.)—This work is said to give more than a hundred thousand stars and nebulae in the positions they occupied on the first day of the year, 1860, according to the highest astronomical authorities in Europe, and is preceded by an explanatory introduction by M. Babinet, of the French Institut.

ANNUAIRE DES SOCIÉTÉS SAVANTES DE LA FRANCE ET DE L'ÉTRANGER. By the Count Achmet d'Hericourt. Two vols., 8vo. (Paris.)—A list of all the learned societies, not only in Europe, but in all quarters of the world, including Oceania.

DESCARTES, SES PRÉCURSEURS ET DES DISCIPLES. By Emile Saisset. 18mo. (Paris.)—The great French philosopher is taken as the starting point, or rather standard, around which M. Saisset has developed his notes and criticisms on the history of philosophy—Bacon, Ramus, Descartes, Spinoza, Malebranche, Leibnitz are the principle figures in the work; but M. Saisset has devoted a large portion of his attention to throwing light on the more obscure portions of Spinoza's philosophy.

LES ASSOCIATIONS OUVRIÈRES DE CONSOMMATION, DE CRÉDIT, ET DE PRODUCTION, EN ANGLETERRE, EN ALLEMAGNE ET EN FRANCE. By Eugène Véron. 18mo. (Paris.)—A small but interesting work on co-operative societies. It has a special value at the present moment, when the Imperial legislature is occupied with a measure for releasing such associations from some of the trammels which now bind them in France.

LE LIVRE DES OUVRIERS A LA VILLE ET A LA CAMPAGNE. By H. Huré and J. Picard. One thick vol.; 12mo. (Paris.)—This is a praiseworthy attempt, by two gentlemen of education, one a professor and the other an officer in the library of Sainte Geneviève, to furnish the working man with a cheap book of reference on almost all subjects. Religion, morals, the duties of workmen and the legislation that specially affects them, reading, writing, grammar, arithmetic, singing, the useful arts, industrial biography, geography, and history are the subjects of the work, which is systematically and not alphabetically arranged.

GUIDE PRATIQUE DE L'INGÉNIEUR AGRICOLE. By Jules Laffineur. (Paris.)—Soil, drainage, irrigation, and all the operations which form the basis of scientific cultivation, are treated in this work.

Notes.

SOUTH KENSINGTON MUSEUM.—The Lords of the Committee of Council on Education have appointed a commission to inquire into the warming and ventilation of the galleries containing works of fine art at the South Kensington Museum. The Commission consists of Prof. Graham, Master of the Mint; Prof. Tyndall, Dr. Percy, Dr. Frankland, Colonel Scott, R.E., and Captain Donnelly, R.E.

ELECTRIC TELEGRAPH.—Algiers is now connected with France by the electric wire. The price of a message from Algiers or Tunis to Paris is eight francs for twenty words, this being only two francs more than the cost of a similar message from Boulogne to Worthing, which is six francs, that is to say, the same as a despatch from Paris to London.

BREAD of this year's wheat was sold in Paris a few days since; of course this wheat was grown in the Marseilles district, which is actually a southern climate.

Correspondence.

SUBAQUEOUS RESPIRATOR.—SIR,—Not reading the *Journal* with that regularity which its contents deserve, it was

only to day that I perused the article "Respiratory Apparatus," in No. 651. It is there stated that M. Galibert has invented an apparatus for affording a supply of air to persons working under water, &c., that is so much like an apparatus invented by my father, illustrated and described by him in the *Mechanic and Chemist*, November 23, 1839, that nearly every reader will see that there is the same train of thought and reasoning for attaining the same end. Without being biassed in its favour, I think my father's invention would obtain the preference, for he suggested that the air-bag should be filled with a mixture of one-thirtieth more oxygen than ordinary air. The copper bag carried on the back is described by him as containing condensed air, which issues gradually and regularly into the hood. With this apparatus a diver, carrying weights round the waist, which he could release when he wanted to come up, would be enabled to explore for a quarter of an hour together the bottoms of canals, lakes, rivers, &c. In thus writing I do so to claim for my father a priority of twenty-six years in this idea.—I am, &c., CHARLES PIERCE.

Proceedings of the Society.

MUSICAL EDUCATION COMMITTEE.

The following is a continuation of the information relating to Musical Education on the Continent, collected by this Committee:—

AUSTRIA.

The well-known Conservatoire of Music at Vienna forms a part of a general association, entitled, "The Society of Friends of Music in Austria," established for the cultivation and promotion of music. The following is a translation of a characteristic official document, setting forth the circumstances which gave rise to the establishment of the Society, and the history of the Conservatoire itself:—

In the year 1811, an association of noble ladies, having for its object the encouragement of works of beneficence and utility, was established in Vienna. This association, which since that period has been in constant activity, was engaged in discussing by what means substantial assistance could be rendered to the inhabitants of the city of war beyond the Danube, as well as to the town of Baden, which had recently suffered from a fearful conflagration, to which end it was requisite to raise from the charitably-disposed contributions to a considerable amount.

Fanny, Baroness von Amstein, one of the leading members of the association, a lady of rare merit and unbounded liberality, conceived the idea of giving a concert on a grand scale, and in a building the most capacious that might be obtainable for the purpose. The well-known instrument maker and pianist, Herr Streicher, suggested the performance of Handel's great work, "Alexander's Feast," with Mozart's additional accompaniments, a selection which was creditable alike to his taste and discernment. His Majesty the Emperor Francis granted permission for the rehearsals to be held in the new "Rittersaal" of the Palace, the concert itself in the imperial riding-school, defraying, moreover, the expenses incurred in fitting up this magnificent building for a concert-room.

With her characteristic activity the Baroness, assisted by Herr Streicher, issued invitations to the votaries of music of all ranks to co-operate in the undertaking. Prince Lobkowitz, an enthusiastic amateur, whose wife was the first lady-president of the association, arranged

for the preparatory vocal rehearsals at his own hotel. The required number of instrumental performers was soon complete, and the first performance of the work, under the title of "Timotheus, or the Power of Music," came off on the 29th of November; the second on the 3rd of December following; Herr Streicher leading on the pianoforte. The Hofrath von Mosel was conductor. The orchestra numbered 720 individuals of all classes, who cordially united in giving this grand musical treat for so praiseworthy an object.

The multifarious arrangements, which were more numerous than it might be supposed, were chiefly carried out by Count Dietrichstein, the treasurer of the Association, and the privy councillor, Herr J. Sonnleithner, whom the Emperor, as founder of the society, had appointed to be its permanent secretary.

A few days before the second performance, Herr Sonnleithner was struck with the idea that, from the general enthusiasm aroused by Handel's great classical work, hopes might be entertained of realising a long cherished desire, namely, to unite the numerous assemblage of the lovers of music into a permanent society, having for its object the encouragement of the art in all its branches, and the foundation of a Conservatoire, which latter had long been a desideratum in Vienna. Great composers had here formed themselves, independently of extraneous aid (gleichsam aus sich selbst gebildet); such an establishment would tend to the development of similar talent, which only needed opportunity to discover its latent powers, and a guiding spirit to direct it on the right course. Now, when a vivid interest was awakened, appeared to be the most favourable, perhaps, indeed, the only opportunity which augured success, but it was necessary that no time should be lost. Herr Sonnleithner drew up a programme, briefly setting forth the advantages to be derived from such a reunion of amateurs, and the formation of a regular society, and inviting those who might be desirous of joining to enter their names in a list, which was opened for the purpose at the hotel of Prince Lobkowitz, by which entry they were only to be bound in case the rules of the society, when drawn up, should receive the Emperor's assent. The proposition was eagerly entertained by those who had taken part in the performance of "Timotheus," and in a few days the number of entries exceeded 1,000. Various motives, no doubt, concurred in bringing about this result; many were desirous of hearing musical works of a high standard brought forward in a manner worthy of their reputation; many were desirous of taking part themselves in the performances; while all were actuated by the laudable wish of aiding in the establishment of a school in which pupils might be fittingly trained. Upon this, the leading object of the Association was declared

to be the elevation of music in all its branches, to which individual practice and enjoyment were to be considered subordinate.

For the attainment of this prime end a Conservatoire of Music was to be established, in which pupils of both sexes from the various Austrian provinces might receive instruction in singing, in declamation, instrumental music, practical thorough bass, in composition, in languages, and other collateral subjects. Works of classical repute, already in existence, were to be performed under the auspices of the Society, partly in order to create a higher standard of musical taste, and partly thereby to awaken germs of talent in the pupils, and to excite in them the desire of obtaining similar distinction in musical composition, in which they would be encouraged by rewards from the association to such an extent as its means would allow.

In 1816 the Association found itself in a position to warrant its proceeding with such an undertaking. Hofrath von Mosel, being requested to draw up a scheme for this purpose, at once undertook the task, and on his plan the course of study was based. It having been laid down as a principle that all the pupils, even those who intended to devote themselves in future to instrumental music, should previously receive instruction in singing—a school for singing was in the first instance organized, and opened on the 1st of August, 1817. In 1819 the violin school was opened, and as the pupils in the singing school had already made considerable progress in their elementary studies, and it became necessary that they should receive instruction in the more advanced stages (which is of an essentially different nature), a third class was instituted for those among the female students whose talents and assiduity held out a promise of higher development. In 1821 the course of study pursued had been attended with such success, that the association began to think of enlarging the establishment, and in order to meet the largely-increasing outlay found it necessary to invite a special subscription, and several liberal patrons put down their names for various amounts for a term of six years. In 1823 the pupils had already made such progress that it was resolved on holding an examination in presence of the assembled members and the public generally, and it was accordingly held in the hall of the Lower Assembly.

An unexpected opportunity for bringing the pupils of the Conservatoire into public notice occurred in 1825, owing to the closing of the Court theatre adjoining the Kärntnerthor. Permission was granted for the performance of two concerts, which were given on the 30th October and 9th November, and met with general approbation. In the same year the students were presented, in the great hall of the society, to its illustrious patron, his Imperial Highness the Cardinal Archduke Rodolph. It was resolved, in order to excite the emulation of the students, to distribute premiums among such of them as showed the greatest proficiency, partly in the form of silver medals, and partly in useful musical works.

The progress made by the Conservatoire induced all those who had given a year's subscription to promise a continuance of the same.

Up to the year 1830 the operations of the Institute were carried on in hired premises, until at length the society, having attained a recognised position, was enabled, by the liberal assistance of its patrons, to acquire possession of the house No. 558, Unter den Tuchlauben, and to undertake the necessary additions thereto. The pupils were now enabled to practise in concert in the music-hall of the Society, their exercises becoming thereby of additional interest. Public performances were given regularly from 1831 till 1847, the proceeds from which were applied partly in establishing scholarships for the more talented pupils and partly to charitable purposes. On two occasions (on the 29th March, 1837, and the 21st of the same month in 1847) the students had the honour of performing in the presence of the Imperial Court. After a short interruption,

caused by the events which occurred in 1848, the sessions of the school were resumed, with certainties which, through the progress of time, became necessary; and notwithstanding many obstacles in the way of their fuller development, carried on to the present time. That its advancement has been behind that of similar institutions in other countries, mainly owing to the disinterested zeal of those who have, for very inadequate remuneration, devoted their professional talents and experience to the education of their successors.

The course of study embraces every kind of education except the organ, for which, until now, space has hitherto been wanting. There is a class for boys, one for girls, two for the piano, one for the violin, and one each for the violone, bass, flute, clarinet, horn, trumpet, trombone, in addition to thorough bass, composition, recitation in German and the Italian languages. The subjects of acoustics, the history of music, and other subjects, for which competent teachers could be obtained free of expense, were, however, omitted for want of sufficient accommodation. In the last ten years the annual number of pupils has been nearly 200, of whom more than two-fifths have received gratuitous instruction; besides these, 50 have each year been refused admission for want of space. There have also always been among the pupils some who have been received into the Conservatoire on special grounds—such as military bandsmen, the asylums for the blind, &c. The annual examinations, the instruction given are brought into not public examinations, which, more especially, have been remarkably well attended. The progress given by the pupils, under the able direction of Hellmesberger, gave evidence—not only of the advance in individual proficiency, but also of the advantage derived from their practising in concert.

Had it not been for the liberal support accorded to the Conservatoire by its illustrious patrons, it would have been impossible for the society to stand the most strenuous efforts, and notwithstanding the unceasing self-devotion of the professors, to place it on an established foundation. In the past it must ever hold in cherished remembrance the names of its earliest patrons—the late Archduke Cardinal Rodolph, who, himself an accomplished amateur, took a deep interest in its success, after whose decease his illustrious brother, the Archduke Victor, was graciously pleased to undertake its protection, and accorded to it numerous liberal contributions in his favour. The society has also to be deeply indebted to his Majesty the Emperor Ferdinand for his annual contribution, for three years, of 3,000 florins, the Imperial Treasury, granted in 1842, and extended for three years in addition, that is, till 1848; and since 1851 it has been in receipt of the favour of the Emperor Francis Joseph for the like annual amount up to the present time. The realization of the advantages derived from the Conservatoire by the Common Council of Vienna, in the year 1851, an annual subscription of 2,000 florins, since then for a term of six years, besides special gifts from the Society for its general utility, has received on various occasions from members of the Imperial family, as from the Emperor's privy purse, and from the pockets of private amateurs.

This document concludes with a list of the names of the vocalists and instrumentalists, of greater or less note in the musical world, who received their education at the Conservatoire. The society is governed by a president, a vice-president, and 12 members, elected for three years, but re-eligible. The Conservatoire is divided into an administrative branch and the artistic branch. The former is governed by a "referent" and 24 members, who divide the different schools into which the Conservatoire is classed; the latter by an artistic director and

of different lengths of service from 43 years downwards. The number of pupils in the year 1863-4, was 109, of whom 199 were males and 110 females; 106 of the number paid no education fees, and 33 half-fees only. The charge for education is described as the smallest existing anywhere.

The following are some of the provisions of the statutes of the general society, the chief objects of which are stated to be (1) the maintenance of a Conservatoire; (2) the public performance of good musical productions; (3) the maintenance of a musical library and its appurtenances; (4) general vocal and instrumental rehearsals and performances of the members; and (5) the encouragement of rising musicians by experimental or public performances of their works or otherwise.

The society consists of honorary and ordinary members, the latter comprising supporting or subscribing (unterstützend) members paying 10 florins* a year (10s. 8d.) of which 4 fl. is applied to the Conservatoire, participating (theilnehmend) members, paying 6 fl., and effective (außerbend) members paying 4 fl. and assisting by singing or playing. A general meeting of the society is held every year for receiving the reports of the directors and other business. The directors of the society have a discretionary power of relieving, wholly or partly, from education fees those of the pupils in the Conservatoire whose means are insufficient, and who prove themselves deserving of such a privilege by one year's attentive study. The directors have also a general control over the affairs of the Conservatoire. The society gives four public concerts a year under the management of the artistic director, besides extra concerts. For the purpose of rehearsal and performance of the members, the society is divided into a vocal union (sängerverein) and an orchestral union (orchester-verein), each of which have the right of using the society's hall once a week free of charge. Each union has to make an annual report to the directors.

The following particulars are taken from the annual report presented to the general meeting of the society on the 21st December, 1864:—

Out of the total number of 309 pupils above mentioned, 17 were in the school for wind instruments, 58 in that for stringed instruments, 118 in the piano school, 35 in the boys' singing school, 31 in the girls' singing school, &c., &c. A pension fund for the professors of the Conservatoire has just been established.

The total receipts of the Society and Conservatoire for the year 1864-5 are estimated as follows:—

1. RECEIPTS OF THE SOCIETY.

	Florins.*
Balance from last year	2,126
Ordinary contributions of members	5,400
Extraordinary ditto	1,000
Receipts from concerts	2,500
Interest on investments	1,131
Rent, &c.	2,400
Out of hall	3,500
Charges for heating and lighting	520
Total	18,577

RECEIPTS OF THE CONSERVATOIRE.

Contributions of supporters (including 3,000fl. from the State, 2,000fl. from the commune of Vienna, &c.)	5,200
Matriculation fees	150
School fees	8,000
Interest on investments	152
Total	13,502
Grand total	32,079

* The florin is equal to 1s. 8d.

The expenditure is estimated as follows:—

1. EXPENDITURE OF THE SOCIETY.

	Florins.
Salaries and fees	2,154
Expenses of concerts	5,000
Interest on mortgage	2,320
Paid off mortgage	2,100
Taxes, &c.	2,250
Cost for heating and lighting	2,100
Library, printing, and miscellaneous expenses	2,640
Total	19,664

2. EXPENDITURE OF THE CONSERVATOIRE

Salaries	9,400
Fees (remunerations)	1,400
Purchase of musical instruments and other expenses	656
Total	11,456
Grand total	31,120

Surplus of receipts over expenditure 959
The assets of the society are stated to include the following items:—

	Florins.
(1.) Balance in hand as above	2,126
(2.) Purchasing price of the Society's old houses	48,080
(3.) Value of the existing house, after deducting mortgage of 46,000 florins	25,800
(4.) Investments (nominal amount)	20,420
(5.) Cash balance at the bank	1,050
(6.) Value of library, musical instruments, furniture, &c.	23,200

The Conservatoire has assets consisting of investments of the nominal amount of 3,200 florins.

The society is just commencing the erection of a magnificent new building for which the Government has granted a site and half the produce of two lotteries. In connection with this structure is to be a great monument in honour of Gluck, Haydn, Mozart, Beethoven, and Schubert, towards the erection of which a special fund of 5,000 florins has been raised.

BOHEMIA.

By an arrangement similar to that adopted in Austria, the association established at Prague, and entitled "The Society for the Promotion of Music in Bohemia," is combined with and directs a musical institute known as the Conservatoire of Prague.

The society consists of three classes of members, viz.:

- (1.) Contributing, paying 40 florins and upwards a year.
- (2.) Effective, possessing musical knowledge, living in Prague and not holding office in the Conservatoire.
- (3.) Honorary.

The society professes to train members of orchestra, solo players, and singers for concerts and stage, and by means of good musical productions to spread a taste for music, giving public performances of the pupils. The society is governed by a president and six members, elected for three years and re-eligible. The statutes contain minute rules for their guidance, and for the working of the society, instructions to the office bearers, &c.

A pension fund is connected with the Conservatoire for giving pensions to the directors, professors, &c., and also to their widows; the necessary funds being raised by an annual per centage on the net receipts of the concerts, &c., &c. The pensions vary from one-half the salary when the service has been under ten years, to the whole salary when it exceeds 20 years; and the widows receive 200 florins a year. The fund is managed by a President, who is the head of the general society, three other members of the governing body of the society, two

professors, and the directors of the Institute. The course of proceeding is defined by statutes. The fund amounted to 8269 fl. at the end of 1864.

The Conservatoire contains an instrumental school and a singing school, divided into a concert school and an opera school, all governed by minute statutes. The yearly report for 1864 shows that the society had thirteen honorary, six effective, and seventy-nine contributing members, subscribing 5,481 fl. It possessed a capital of 20,947 fl. The receipts for 1865 (including a balance in hand of 2,363 fl.) are estimated at 13,820 fl., of which 4,200 fl. is a subvention by the Government from the "Landesdomestical" fund, 5,349 fl. subscriptions, 900 fl. interest, 500 fl. net produce of concerts, and the rest miscellaneous. The expenses are estimated at 12,432 fl., viz: 6,704 fl. salaries, 2,075 fl. allowances, 915 fl. pensions, 690 fl. taxes, &c.

The Instrumental School where the term of education is six years, contained 57 pupils in the 1st class admitted in 1861, and 43 pupils passed out of the Conservatoire as qualified in the 2nd or higher class admitted in 1858; of these 43, 27 at once obtained appointments in orchestras, &c. The Opera School, with an education of from two to three years, contains five females and one male, and the Concert School, where the term of education is two years, 10 female pupils. All the pupils receive a general as well as a musical education. Three concerts, producing 606 fl. net, were given in the year 1864. The education is gratuitous for natives in all the schools. Foreigners pay 60 fl. a year in the Instrumental and Concert schools and 80 fl. in the Opera school.

Proceedings of Institutions.

ABERSYCHAN LITERARY AND SCIENTIFIC INSTITUTION.—The report for the past year, read at the annual meeting of the members, on the 27th February last, congratulates the members on the favourable position the society has attained in this the first year of its existence. Thanks to the proprietors of the works at this place, and to their manager, Mr. Richards, a room has been provided and set apart for the purposes of the Institution; and everything to adapt it to the convenience of the members has been provided by them free of cost. In February, 1864, the first meeting of the society was held. In the first quarter the number of members reached about seventy, and this number has been steadily maintained throughout the year. The books purchased by the society during the year number altogether 92 volumes. The issue during the year has not been large, numbering about 140 volumes, with a proportionable number of periodicals. The financial statement shows that the income has amounted to £54 7s. 7d., and that there is a balance in hand of £13 18s. 11d.

ASHTON AND DUKINFIELD MECHANICS' INSTITUTION.—The last report shows that the number of members is increasing, and the directors have spared no pains to meet that increase by increased attractions. In the early part of the year the directors opened an Exhibition of Paintings and Works of Art. The exhibition was open three days, and gave general satisfaction. The discussion society, which meets on alternate Monday evenings, is well attended, and its meetings are a source of great interest to its members. A chess and draught club has also been established. Both these societies are open to the members on payment of a small annual subscription. The number of members was 551 at the date of the issue of the report, showing an increase of 31 over the former year. The classes now in operation are:—Writing, arithmetic, grammar, geography, and mathematics; present number of members, in senior class, 60; in junior class, 52; French, mechanical, architectural, and freehand drawing. The Committee of Council on Education have awarded the Bronze Medal of the Art Department to

several pupils. The present number of volumes in the library is 3,616, being an increase of 146 over the previous year; the total number of issues is 7,416. In the reading and news room reports from the Liverpool cotton market, and from the leading corn and produce markets are regularly laid upon the telegram stand, so that those interested in trade may obtain information which will prove of value to them. The financial statement shows that the receipts have amounted to £315 13s. 11d., and that there is a balance in hand of £4 14s. 6d.

BURNLEY MECHANICS' INSTITUTION.—The report for last year says that the continued depression of trade has rendered it expedient that the efforts of the directors should almost be exclusively directed to maintain unimpaired the usefulness of the leading departments of the Institution. The circulation of books for the year amounts to 7,660 volumes, and the total number of volumes in the library is 4,486. The class registers show in the aggregate a small decrease in the number of members, the number of males being 150, females 44; total, 216. In 1863, the numbers were—males 177, females, 47; total, 224; decrease of males, 27; increase of females, 19; making the absolute decrease since 1863 to be 8. In the manufacturing districts of Lancashire where the demand for female labour is such that girls are removed from school or domestic employment at an early age, a well-devised system of secondary education for females is of the greatest social importance. The directors have been desirous to make the female classes attractive, and adapted to their special duties. A series of lectures and conversations, by Dr. Brumwell, on Domestic Affairs, and subjects intimately connected with them, have been held for the benefit of the members of these classes and their female friends. Generally the attendance of the members at the classes has been regular, and their progress commendable; these remarks especially apply to those who entered the various examinations during the year. In the year 1863 the number of members was 364; in the year 1864, 347; decrease, 17. Out of the 17 removed from the list, 15 have become subscribers to the Exchange, so that although not counted, they still remain members of the Institution. The Exchange register exhibits a large addition of subscribers, the numbers being, residents, 249; non-residents, 155; total, 414. In 1863 the numbers were, residents, 219; non-residents, 88; total 309. Increase in the year 1864, 105. This remarkable increase of subscribers, and the consequent crowding of the room on market-days, rendered larger space and increased accommodation necessary; this has been supplied. The financial statement shows that the income has been £498 8s. 9d., and that there has been an excess of expenditure amounting to £5, which may be ascribed to the large outlay on the improvement of the Exchange, and to the absence of the usual item of profit arising from a public soirée. About the time of making arrangements for this festival the state of trade was so appalling, that the directors decided that it was inexpedient to hold a soirée under such circumstances.

EXAMINATION PAPERS, 1865.

(Continued from page 538.)

The following are the Examination Papers set in the various subjects at the Society's Final Examinations in April last:—

MENSURATION.

THREE HOURS ALLOWED.

1. Prove that a rain-fall of an inch gives about 1¹/₂ tons to the acre. What would a fall of a centimetre be to the hectare?
2. Show how to measure a given parallelogram. The perpendicular distances between the opposite sides of a parallelogram are to be two and three inches: find the

area of the least parallelogram which satisfies this condition; and construct another which is twice this area, and satisfies the same condition.

8. Explain the construction and use of the *diagonal scale*.

4. Find the area of a right-angled triangle, one side of which is 15 inches, and the hypotenuse $3\frac{1}{2}$ feet.

5. A rectangle is 8ft. 6in. long, and 4ft. 9in. broad, find its cost at 1s. 6d. per foot, by duodecimals.

6. Draw a plan, and find the area of a field from the following notes :—

444 to A
182 264
From C on R

386 to C
From B on R

564 to B
From A

7. Prove that the perimeter of a square is less than the perimeter of a rectangle of the same area.

Find the least number of hurdles, each 2 yards long, which will enclose an acre of land of rectangular shape.

8. Find the cost, at £6 15s. per rod, of the outer walls of a house 86ft. wide, 28ft. 6in. deep, and 86ft. to the roof, there being a gable at each end, rising 32 courses of bricks, reckoning 4 courses to a foot, the first 12ft. being 2 bricks thick, the next 15 being $1\frac{1}{2}$, and the rest 1 brick thick.

9. Find the area of a circle whose diameter is 118 inches, and circumference 365.

10. Find the diameter of a 600-pound cannon ball whose specific gravity is 7.2.

11. The curved surface of a circular cylinder is 10ft., the areas of its two ends the same as that of a circle 10in. in diameter: find its volume, and the weight of the water which it will contain.

12. Prove that the volume of any pyramid is equal to one-third of its base into the height.

TRIGONOMETRY.

THREE HOURS ALLOWED.

1. Find the circular measure of $2^\circ 4'$ French and of $1^\circ 50' 59''$ English.

2. Prove that $\text{Sin. } 2a = \frac{2 \tan. a}{1 + \tan. a^2}$
And that $\text{Cot. } (a-b) = \frac{\text{Cot. } a \text{ Cot. } b + 1}{\text{Cot. } b - \text{Cot. } a}$

3. If A B C be a triangle, sides a b c, then $c^2 = a^2 + b^2 - 2 ab \cos. C$. Adapt this to logarithmic computation.

4. A B C is a triangle, and A D meeting the base in D divides angle A into two angles, m and n, so that $\frac{\text{Sin. } m}{\text{Sin. } n} = \frac{c}{b}$

Prove that $\text{Cot. } m - \text{Cot. } n = \text{Cot. } C - \text{Cot. } B$; the angle B A D = m.

5. Prove that—

$$(1) \frac{\text{Sin. } (2a+b)}{\text{Sin. } a} = 2 \cos. (a+b) + \frac{\text{Sin. } b}{\text{Sin. } a}$$

$$(2) \text{Cosec. } 2a + \text{Cot. } 4a = \text{Cot. } a - \text{Cosec. } 4a.$$

6. Find a when

$$(1) \text{Sin. } 5a = 16 (\text{Sin. } a)^5$$

$$(2) \text{Sin. } a + \text{Sin. } 2a + \text{Sin. } 3a + \text{Sin. } 4a = 0.$$

$$(3) \cos. a - \cos. 2a = \text{Sin. } 3a.$$

7. If A B C be the angles of a triangle—

$$(1) a (b \cos. C - c \cos. B) = b^2 - c^2$$

$$(2) \frac{\tan. A}{\tan. B} + \frac{\tan. B}{\tan. C} + \frac{\tan. C}{\tan. A} = \frac{\tan. C}{\tan. B} + \frac{\tan. B}{\tan. A} + \frac{\tan. A}{\tan. C}$$

$$+ \frac{\tan. A}{\tan. C} = \text{Sec. } A \text{ Sec. } B \text{ Sec. } C - 2.$$

8. In a right-angled triangle $C = 90^\circ : c = 7584 : b = 8000$; find B, when

$$\log. 7584 = 8798983 : \log. 2 = 30103$$

$$\log. \sin. 34^\circ 59' = 9.7584105 : \text{diff. for } 1'' = .0001805$$

9. A D and B E are perpendiculars from the angles A and B of the triangle A B C on the sides opposite. Show that $D E = c \cos. C$.

10. The radius of the circle inscribed in a triangle,

$$= a \sin. \frac{B}{2} \sin. \frac{C}{2} \sec. \frac{A}{2}$$

11. Sum the following series to infinity—

$$\text{Sin. } a + \frac{1}{1.2} \text{Sin. } 2a + \frac{1}{2.3} \text{Sin. } 3a, \&c.$$

12. The elevation of Cader Idris, at a point in the valley near Dolgelly, is $\text{Cot. } .16$; at Ty Gwyn, $8\frac{1}{2}$ miles down the valley, it has the same elevation; at a point half-way between, its elevation is $\text{Cot. } .15$. Show that its height above the valley is $\frac{7}{\sqrt{11}}$ miles.

13. In a spherical triangle find the sine of the angle in terms of the sides.

14. Find the area (s) of a spherical triangle in terms of its angles.

15. And then show that—

$$\text{Cot. } \frac{s}{2} = \text{Cot. } \frac{a}{2} \text{ Cot. } \frac{b}{2} \text{ Cosec. } C + \text{Cot. } C$$

16. Given B, a and b, and $\text{Cot. } \theta = \cos. b \tan. a$,

$$\text{Prove that } \text{Sin. } (c + \theta) = \cos. b \sin. \theta \sec. a$$

CONIC SECTIONS.

THREE HOURS ALLOWED.

SECTION I.—GEOMETRICAL CONICS.

1. Define a cone, a parabola, the focus of a parabola, the diameter of a conic. Show that in a parabola the sub-normal is constant, and the sub-tangent is double of the abscissa.

2. In the parabola prove that $NP^2 = 4AS \times AN$.

3. Tangents which meet on the directrix of a parabola are at right angles to each other; and the line which joins the points of contact passes through the focus.

4. Define tangent of an ellipse, and prove that the tangent of an ellipse is equally inclined to the focal distances of the point of contact.

5. The normal at a point P of an ellipse meets the major axis in G and the minor axis in G'; prove that

$$PG : PG' :: CB^2 : CA^2$$

6. The rectangles contained by the segments of two intersecting chords of a central conic are as the squares of the parallel semi-diameters.

7. If a perpendicular is drawn from the focus of a hyperbola on a tangent, the point of intersection lies in the auxiliary circle.

8. Prove, by Projection or otherwise, that in the hyperbola

$$NP^2 : AN \times NA' :: CB^2 : CA^2.$$

9. Define asymptotes of a hyperbola; and construct them geometrically when the hyperbola is given.

10. If an ellipse is defined as the section of a cone by a plane, find, by geometrical construction, the centre, foci, directrices.

11. If a circle is projected into a central conic, show that the diameters which are parallel to a pair of supplemental chords are conjugate to each other.

SECTION II.—ANALYTICAL CONICS.

12. Determine the equations to the straight lines passing through the origin, and making an angle of 45° with the line $ax + by + c = 0$.

13. Find the equations to the internal and external bisectors of the vertical angle of a triangle; and show

The inspectors also visited 89 separate training colleges, occupied by 2,789 students in preparation for the office of schoolmaster or schoolmistress. In December last these students, and 1,767 other candidates, were simultaneously examined for the end of the first or second year of their training, or for admission, or for certificates as acting teachers.
